never say die

Vegas

A letter from the Sahara Hotel explained that I could come if I wanted to, but that under no circumstances was there to be any controversial discussion. This kind of substantiated my suspicion that this was not a convention at all, but a thinly disguised excuse for hams to come on out and enjoy girls and gambling. I'd rather buy a new rig.

Sunspots

Now that the present cycle is well on its way upward the experts are watching it carefully, trying to estimate just how high it may actually go. It has already surpassed the prediction made by George Jacobs W3ASK who thought it might peak out at 60-70 and now looks as if it will top off in the 140-150 range. What does all this mean for us? Well, the bands will be hot . . . ten will be wide open a lot now, twenty will frequently be staying open all night . . . conditions are definitely looking up.

Pot shots

Huntoon has been pegging off shots at me in QST lately. In the August issue he reported an IARU censuring movement against an unnamed amateur radio magazine, strongly implying that it was 73. I wrote directly to the party who instituted the censuring movement and have a letter from him stating that this was against another amateur magazine, and not 73. Tsk, tsk . . . yellow journalism.

Huntoon is still trying to sweep unpleasant facts under the QST carpet. He appears quite upset in the December Leaky Lines and calls some poor amateur who wrote in "anti-League." John, I don't think that any of us are really anti-League. There are a number of us, a growing number, who are disappointed

in the way the League is running things, but is this a reason to lose your temper and call names?

John, a large number of us are seriously worried about the future of amateur radio and think that something concrete should be done to get more world support for our hobby. We want to know that the League realizes this situation and that it is doing something positive to influence the outcome. Yet we hear of

little being done.

Now, about the 14,000 ARRL members lost last year. First of all I would like to say that I feel responsible for anything that I write and publish . . . I also assume responsibility for anything that I say. But I do not feel that I should be held responsible for something that someone else says I said. In this particular case I was not quoted at all correctly. However, lest anyone think I am trying to weasel out on something, let's just put aside all those pretty little figures that you've trotted out to confuse the unwary . . . and shame on you for doing that, John . . . was that really honest?

The question has been raised about how many members the ARRL lost in 1965. ARRL members, if they want to invest an interesting 75¢, can send for the 1965 Annual Reports. John realizes that very few amateurs do send for this document and thus writes freely. John cannot plead ignorance of the actual figures for they appear in his own personal report to the Directors. In paragraph 5 of his report we find that 18.4% of the ARRL members in the U.S. and possessions did not renew their membership in 1965. In paragraph 4 we find that there are 78,180 full members and 8,753 associate members as of the end of 1965, a total of 86,753 members (subscribers). 18.4% of that is 15,962 subscribers lost in 1965.

Now the bulk of those lost subscribers were replaced by new subscribers so that the *net* drop in overall membership of the League was only 1,214. This all comes from John's report, so let's see if he has anything but a very red face to show on the subject now.

DX thoughts

A letter from an SM complained about the lack of courtesy of the U.S. stations when they are after a rare DX station. I've heard this complaint for a lot of years now and I was rather surprised when I got on from KC4AF a few years back and found everyone to be just as cooperative as I could ask. I had virtually no problems with bad manners from

Editor's Ramblings

Paul Franson WA1CCH

VHF frequency pressure

Businesses in this country badly need additional VHF frequencies for their two-way communication. Many of the channels allotted to them are hopelessly overcrowded. Two-way users in heavily populated areas often have long waits before their channels are free enough to pass even short messages. Yet other frequencies lie almost unused in the same areas because they are assigned by service rather than location. Agricultural channels are little used in metropolitan areas while more urban channels are jammed.

These inequities should be straightened out, of course. But that won't solve the whole problem. Two-way users simply must have more channels. The question of where these frequencies will come from is a vital one to hams. A few years ago, it seemed inevitable that at least part would come from the VHF ham bands. We could hardly complain with much justification in view of the small use these wide bands get. But things are looking up for hams now. We may not have to lose any VHF frequencies after all. Our possible saviour is an unlikely-seeming one.

Let's go back a few years to see what happened.

In the forties, when it was apparent that television was going to be feasible commercially, frequencies had to be allotted to it. The decision was made to assign channels in what is now our VHF TV band. Time has shown that this was a bad decision and that it would have been better to have allotted higher frequencies, but then no one was able to convince officials how popular TV would be, and how much interference the VHF TV channels (particularly the low band ones) would suffer during periods of favorable propagation.

So the channels were assigned and stations started broadcasting. It wasn't long before it was obvious that there simply weren't enough channels for all the cities that wanted TV, and all the interests that wanted to own TV stations, so additional frequencies were added in the present UHF TV band. Plenty of frequencies were made available so that there were 70 UHF channels and 12 VHF. Some UHF stations went on the air, but most suffered serious financial problems and many closed down. They had a number of strikes against them. First, most TV receivers couldn't receive UHF. UHF was an optional accessory, and many people wouldn't pay extra for it. Others who already had TV's wouldn't spend the money for a UHF converter and antenna, so watched the VHF channels by default even if there was a UHF station near them.

Also, UHF has a more limited range than VHF for the same power and equivalent antennas. Early UHF front ends were very noisy and unsatisfactory unless supplied with a strong signal. Thus UHF stations had a smaller audience than VHF and while the VHF stations prospered, UHF stations did poorly in most areas—especially if they had VHF competition.

In a belated realization of the mistake in not putting TV on UHF in the first place, the FCC made some attempts to help the UHF broadcasters. One plan was to have all TV areas either VHF or UHF without any mixing. This was obviously an unsatisfactory scheme in well-populated regions where other stations might be receivable, and you can imagine what the reaction of the typical VHF broadcaster to this idea was. This plan was squelched. Part of the impetus for the squelching came from Congress since many Congressmen and other government officials have interests in broadcasting stations.

Finally the FCC and others decided that a better answer was to insure that all TV sets could receive UHF. This would reduce the competitive advantage of VHF somewhat, especially since improved broadcasting and receiving techniques (high power transmitters,

(Continued on page 108)

Integrated Circuit Crystal Calibrator

This calibrator generates 10 and 100 kHz markers. It costs less than \$13.

The crystal calibrator ranks with the SWR bridge and code practice oscillator in coverage in the various ham magazines. The names have ranged from the obvious "crystal calibrator" to the less obvious "transistor secondary frequency standard" and "multical". The type of circuitry involved has likewise ranged from simple tube circuits to more complex solid state digital circuits.

The IC crystal calibrator could be considered one of the more complex of the above listed calibrators, providing 100 kHz and 10 kHz outputs. Because of the use of integrated circuits instead of transistors, it is, however, one of the simplest and cheapest. The one described was built for under \$13.

NOR gates and flip-flops

QST, July 1965.

For those who don't have W1CFW's excellent article on the Micro-Ultimatic,³ the oper-

¹ Grigg, "A Transistor Secondary Frequency Standard",

³Davisson, "The Multical", 73 Magazine, October 1966. ³Pickering, "The Micro-Ultimatic", 73 Magazine, June ation of the two basic logic elements are reviewed.

The truth table shows all possible combinations of inputs (A and B) and the resulting output (Q) for the NOR gate. The Fairchild $\mu L914$ contains two of these gates in one package.

A	В	Q	
L	L	H	
\mathbf{H}	L	L	
L	\mathbf{H}	L	H = high $L = low$
H	H	L	L = low

Notice that a high output occurs only if botl inputs are LOW.

Any other combination produces a LOW output.

The truth table for the flip-flop is as follows

S	C	Q
\overline{H}	L	H
L	\mathbf{H}	L
L	L	Reverse
H	H	No change

Fig. 1. Block diagram of K1DCK's crystal calibrator. Output is both 100 kHz and 10 kHz and total cost is under \$13.

G-3

The states S and C are considered before the trigger has occurred, and Q is the condition of the flip-flop after the trigger occurs with a given S-C combination. The flip-flop has two states. It is SET when Q is LOW. It is cleared when Q is HIGH. Another input, called PRE-SET, can be used to make Q LOW regardless of its state and without a trigger.

Binary number system

For the following discussion, forget that 1 and 1 is 2 and we can clear up the last bit of theory needed to understand the operation of this calibrator. To simplify large digital computers, a number system was evolved that contains only two digits (0 and 1) rather than ten digits (0 thru 9).

To see how this system works, think of the odometer on your car and imagine each wheel on this odometer using only two numbers-0 and 1. As the car sat on the showroom floor, the mileage might have read 0000. When you drove it off, registered the first mile (and lost \$1000 resale value), it would read 0001. Okay so far. But when you register the second mile and the right wheel on the odometer advances one more place, a zero appears again since that is the only other number! This second mile clears the first wheel back to zero and advances the second wheel to one. So now the odometer registers 0010. This represents the decimal number two in the binary system. The third mile would read 0011. The fourth mile turns the first wheel to zero, which turns the second wheel to zero, which advances the third wheel to one, and so on. With only four wheels on the odometer, we could register up to 1111 which would be fifteen miles. The sixteenth mile would register as 0000, so we would need a fifth wheel for this number (10000). A list of all the binary numbers from zero thru ten is shown below.

0	0000	6	0110
1	0001	7	0111
2	0010	8	1000
3	0011	9	1001
4	0100	10	1010
5	0101		

These binary numbers are called binary-coded decimal or simply BCD.

Pulse generator

The output of the pulse generator is a 100 kHz pulse. The high to low transition will be used to trigger the counter. The idea of using the μ L914 as a crystal-controlled pulse generator is from a Fairchild application note. With

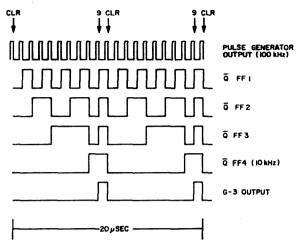

Fig. 2. Waveforms of various points in the BCD counter. Peak-to-peak voltages will vary from one to three volts.

the values shown in Fig. 1, the circuit works well with any of the surplus crystals in HC13/U holders advertised in "73". Another crystal in an HC6 case (also surplus) worked with different values of C1 and C3. Juggle them around; you can't hurt anything.

For those of you on a tight budget, stop here. You have just constructed the cheapest and most reliable 100 kHz calibrator anywhere! However, for those of you who aren't afraid of the XYL, we'll add on the counter/divider.

BCD counter

Sometimes called a divider, this circuit has the ability to count to nine and reset to zero on the tenth count. It is called a divider, because for every ten pulses at its input, it produces one pulse at the output—division by ten. Naturally, for every 100,000 pulses at the input, the output will be 10,000 pulses: the 10 kHz marker. Any inaccuracy in the 100 kHz pulse is divided by ten also, but the percentage of error remains the same.

Looking back at the odometer example, each wheel had two states—ZERO and ONE. A flip-flop also has two states—SET and CLEAR. So flip-flops can easily be substituted for wheels, making a counter which counts in exactly the same way the odometer did. But

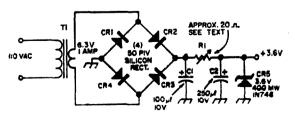

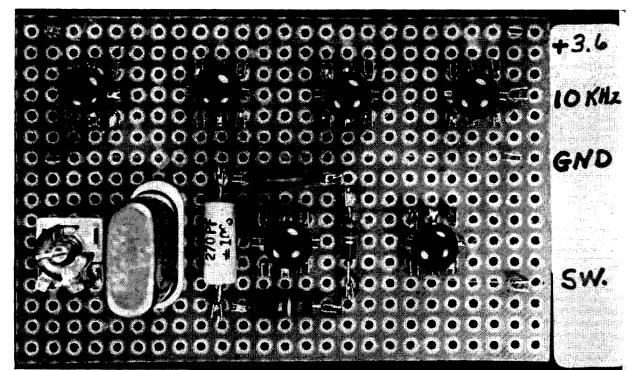

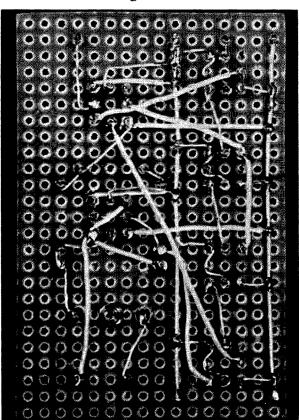

Fig. 3. W1CFW's power supply. Also see Fig. 8 on page 14 in the December 73.

Photos by Harvey Benoit, Haverhill, Mass.

Top, left to right—FF1, FF2, FF3, FF4. Bottom, G1/G2, G3/G4.

this counter counts to fifteen! The counter is fooled into thinking it has reached fifteen

View of the underside of the board, showing wiring. The right bus is +3.6 V. The bus near the center is ground.

when, actually, it has only reached nine. The action of G-3 does this.

In the binary system, nine is 1001 and fifteen is 1111. The states of the flip-flop when it reaches nine are as follows:

FF	Q
FF1	H
FF2	L
FF3	L
FF4	Н

To make the counter think it has reached fifteen, G-3 will go H and preset FF2 and FF3, changing Q to H. This is done by applying Q output of FF1 and FF4, both of which are LOW at this time, to the input of G-3. FF1 and FF4 are SET only when the counter has reached nine.

Power supply

The calibrator draws 80 mA at 3 volts and 95 mA at 3.6 volts. A power supply similar to WICFW's may be used and is reprinted in Fig. 3. Adjust R1 for 20 mA zener current,⁴ under load. The separate power supply is recommended since tube-type receivers will not have suitable voltages available. The power supply won't be very big; if you have a tube-type receiver, you're probably not that finicky about miniaturization anyway.

Ashe, "Zener Diodes", 73 Magazine, October 1966.

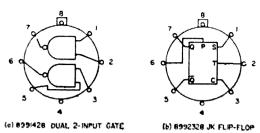

Fig. 4. Bottom view of Fairchild gate and flip-flop IC's. The right side of the gates should be curved.

Construction

The details used in this project are clear enough in the photographs. Flea clips are mounted on a piece of Vectorboard about 2½ x 3½ inches. No attempt at miniaturization was made, so you may want to try. The crystal socket and trimmer were mounted, then all the wiring underneath was done. The large bus across the middle is the ground bus; and the one at the top is the +3.6 voltage. Wire pin 4 of every can to ground and pin 8 to the +3.6 voltage. Pin connections are shown in Fig. 1. Wiring is point-to-point; and teffoncovered wire was used for crossovers. The IC's were then mounted using normal precautions with semiconductors. On some of the earlier epoxy units, pin 8 was identified by a red line; it is identified by a flat spot on present units. The Fairchild UX8991428X is used for G-1/G-2 and G-3/G-4. Fairchild UX8992328X's are used for FF-1 thru FF-4.

Operation

The output of the calibrator may be connected thru a small capacitor, or "gimmick", to the antenna terminal of your receiver. As many receivers have provisions for a plug-in calibrator, the capacitor may already be in. My NCX-3 uses a 6-inch piece of coax. One end of the center conductor is connected to the output of the calibrator and the shield on the other end is connected to the antenna terminal. The small capacitance between the inner and outer conductors makes the small coupling capacitor.

There are two ways to turn the calibrator off when not in use. One is to put a switch in the primary of the power supply transformer. Don't switch the +3.6 voltage. Operating the power supply without a load may damage the zener. Another way is to make use of G-4. Fig. 5 shows how this may be done. With pin 5 always LOW and pin 3 open, the output of G-4 is HIGH. This HIGH has no effect on the operation of the 100 kHz oscillator. If this point goes LOW, then pin 6 will be clamped LOW and the oscillator stops. This

Fig. 5. Gated on/off switch.

point will be LOW if pin 3 is HIGH, which would be the case if the switch were in the OFF position.

Harmonics were quite useable up to 30 MHz. It's possible they may be heard on six meters, but no receiver for this frequency was available. In the event the harmonics are not useable on six, this should present no problem, since the calibrator could be hooked into the antenna terminal of the HF receiver. The harmonics would certainly be heard on the frequency used for the converter *if*. Of course, this scheme would work for any of the VHF bands.

This calibrator points out several of the advantages of integrated circuits. It is small in size and cost, but big in performance. Since it "flew" right off the drawing board, and is easily duplicated, the ease of circuit design is apparent.

. . . K1DCK

Where to Buy Fairchild Semiconductors

Fairchild Semiconductors are very popular with many ham experimenters and engineers, as can be seen from the many articles in 73 that specify them. But none of the large, well-known national mail order distributors that go after the consumer trade seem to carry Fairchild. Nevertheless, Fairchild has an extensive network of excellent and very large industrial distributors. Hams who don't work in the industry may not be familiar with them, but these dealers carry very large stocks and are usually very pleasant to deal with even though their sales to individual hams are a very, very small part of their business. You can get a list of Fairchild distributors from Richard Molay WA6KGS at Fairchild Semiconductor, 313 Fairchild Drive, Mountain View, California 94041.

One Fairchild distributor that has indicated that they're happy to handle mail orders from individuals is Cramer Electronics, 320 Needham Street, Newton, Mass. 02164, and 60 Connolly Parkway, Hamden, Conn. A call or letter to them will give you current prices on any Fairchild semiconductor.

Some Notes on VHF Transistor Converters

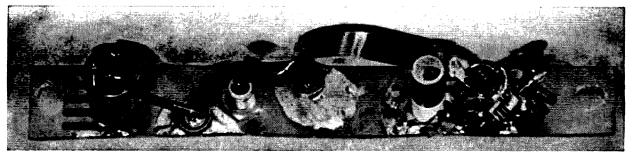

Frank discusses some problems with the popular TIXM05 transistors, adds some notes on newer transistors, and describes an improved 220 MHz converter in this article.

The transistor converters, described in the June 1966 issue of 73, using the low cost TIXM05 transistors have brought a great many inquiries about the source for these little gems. Personally, I'd like to know myself as after the first purchase from a Texas Instrument (TI) distributor of a few TIXM05's, my next request was back ordered for six months and still no delivery. Finally I received several dozen TIM10 transistors which were supposed to be an improved type in the same price range. The breakage problem with the plastic cased transistors seems to be solved, and the characteristics were much more uniform. The "forward gain" characteristics were much better also but all this added up to some changes in circuit values, and even in type of circuits, particularly at 432 MHz. The "X" in the TI transistors apparently stands for experi-

Fig. 1. Forward gain control for one or two rf stages. R should be 510 for an 8-volt supply, 620 for 9 V, and 1000 for 10 V.

mental type which may not be produced in large numbers. The writer will shun those types in future magazine articles, having been "burned" once is enough.

The TIM10 transistors that I've tested so far in the 50, 144, 220 and 432 MHz. converters do not have quite as good a noise figure as a few selected TIXM05's, particularly at 432 MHz. However, at approximately a half dollar cost, they are excellent values, being quite superior to the three dollar types such as the 2N2398's. The forward gain characteristics and higher collector current requirements seem to have been met by the circuit values shown in Fig. 1. The 5000 ohm "pot" permits adjustment of gain for difference antennas, power supply voltages over a limited range, and cross-modulation problems in some receiving locations. The collector series resistors for dc voltage drop should be around 500 ohms for the TIM10 rf stages with a dc supply of 8 to 9 volts. For 10 volt supply a 1000 ohm collector resistor will give greater gain control and 1500 to 2000 ohms could be used for even better results with a 12 or 13 volt supply. The emitter resistor in all cases should be around 500 to 600 ohms. The base bias resistors, two fixed and one variable, should be fairly satisfactory for 8 to 12 volt supplies. The TIM10 transistors will work satisfactorily on any of the VHF bands without neutralization if the base input impedance is kept to 50 ohms or less and a variable gain control is available to keep them below the oscillating points. Too high a collector load impedance will also cause oscillation problems. At 50 and 144 MHz, sometimes a 3900 or 5100 ohm ¼ watt resistor can be wired across the collector tuned circuit to keep the load impedance within reason. A great deal depends upon shielding between stages and the effectivenes of rf bypass capacitors. Sometimes parallel capacitors of 500 or 1000 pF can be conected from emitter to nearby copper plated ground points with short

432 MHz preamplifier using the new Motorola EL229 in a grounded emitter unneutralized circuit. Note that the EL229 is an NPN transistor, while the TIM10 is PNP.

leads to cure a stubborn rf oscillation.

Most of the new transistors such as the Motorola EL 229 and the Texas Instrument TIM10 types are much more stable at 432 MHz when used in grounded emitter circuits as compared to the older grounded base designs. The grounded base circuits are inherently regenerative and require heavily loaded circuits and critical base bias adjustments. This regenerative effect was necessary with older types of transistors to get good results at 432 MHz. The new types apparently have smaller capacitances and usually will not oscillate at 432 MHz when used in grounded emitter circuits with no neutralization. Grounded emitter circuits can be neutralized at lower frequencies where higher input and output impedances will mean more gain and possibly lower noise figures. Grounded base circuits are real "blankety-blank" things to neutralize, as theory would indicate.

The new experimental Motorola EL229 plastic cased transistor will probably cost more than the TIM10 but is a real gem on 432 MHz. The noise figure checked within 1 to 2 dB of that obtained with a parametric amplifier which had a 1600+ MHz pump oscillator. The apparent noise figures were compared by using a weak signal generator connected to each rf amplifier thru high quality 50 ohm 10 dB pads. A similar 6 dB pad was connected in the output of each of the two rf amplifiers into a reasonably stable 432 MHz converter with its rf stage. A comparison of microvolts input in the two cases gives a pretty good idea of the actual noise figure of the rf stage under test. The transistor pre-amplifier shown in the photograph on a long narrow copper plated strip and in Fig. 2 uses an EL 229 in a grounded emitter unneutralized circuit. Its perormance indicated that transistor development is catching up with diode parametric amplifiers. The latter are highly regenerative and costly as compared to the simple transistor rf amplifier shown in the photograph and in Fig. 2. The EL 229 is a NPN transistor so can not be compared easily with a PNP TIM10,

etc. Separate rf amplifiers designed for the TIM10 seemed to show from 1 to 2 dB poorer noise figure than the EL 229. The EL 229, with about 1200 MHz f_T , was better than the very expensive 2N3783 PNP transistor, which in turn was better than the TIM10 units tested here so far.

Let me emphasize the fact that I think the EL 229 is an experimental transistor and may not be available yet at Motorola transistor outlets. I've heard a rumor that it will be about a dollar in price. The experimental rf pre-amplifier in the photograph was built on a scrap piece of copper plated plastic board %" wide and 6" long to fit into a small space available near the regular 432 mc converter. The transistor has three wire leads in line, with emitter in the center to give some added isolation between the base and collector circuits. The EL 229 transistor was soldered directly into the circuit using a cooling clamp between the transistor case and the point of soldering to the wire lead. The base input impedance is approximately 50 ohms at 432 for best noise figure, so was connected to the coax input jack thru a 300 pF coupling capacitor to isolate the base bias circuit from the grounded antenna. A small four turn coil of #20 wire about 5/16" long and %" diameter tends to tune the input capacity of the transistor to 432 MHz. It also tends to short out if band

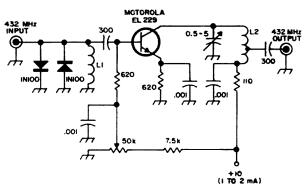

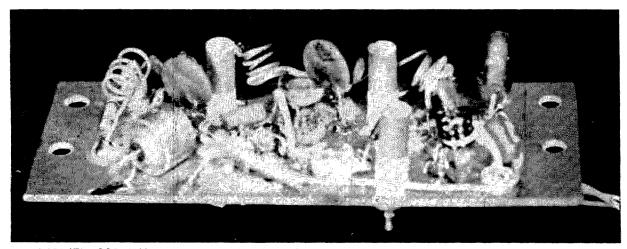

Fig. 2. Low noise 432 MHz preamplifier. L1 is 4 turns #20, 5/16" long x 1/3" diameter. L2 is 2" of a 3/16" wide copper strap bent into a U. Tap up about 1/2".

W6AJF's 220 MHz converter using TIM10's. It's built on a 2" x 5" piece of copper-clad board. See the article on a 220 converter in the June issue for more information.

feedthru signals. The collector circuit consists of a 2 inch long by 3/16" wide piece of copper strip soldered to the tuning capacitor and transistor at one end and to a 1000 pF feedthru bypass capacitor at the other end. These little A-B solder-in feedthru capacitors are very good up thru 432 MHz but are hard to find since they are a manufacturer's item. The slightly larger 500 pF button feedthru capacitors which are used in surplus gear are not bad at 432 MHz. A small 300 pF disc capacitor was connected in parallel to the 1000 pF feedthru capacitor to add a little rf "cooling" to the emitter. The small 5000 ohm pot was adjusted for best signal-to-noise re-

ception which occurred at a collector current of between 1 and 2 milliamperes. The output coax jack used capacitance coupling on a tap about ½ inch from the by-pass capacitor in the collector circuit. Link coupling is another possibility.

Connection of this pre-amplifier as well as a couple of other rf grounded emitter 432 MHz units to a diode noise generator, with or without a 6 dB pad, resulted in a curious noise figure effect. The collector circuit always had to be tuned to a lower frequency (more tuning capacity) for best noise figure measurement in the output of a 14 MHz if receiver. Two types of diode noise generators were used with

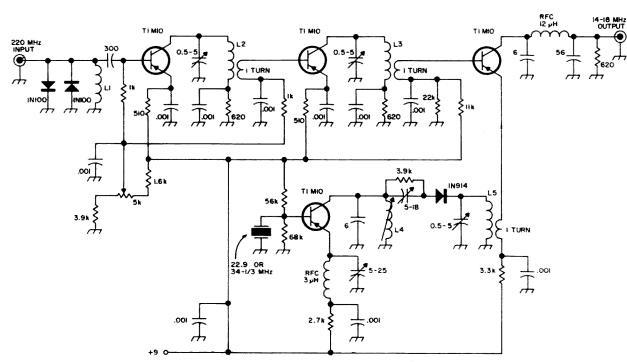

Fig. 3. 220 MHz converter built on a 2" x 5" copper plated board. L1, L2, L3 and L5 are **each** 4 turns #18 wire $\frac{1}{4}$ " in diameter. L1 is $\frac{1}{2}$ " long and the other three are $\frac{3}{8}$ " long. L4 is 11 turns #24 enamelled on a $\frac{1}{4}$ " form with a brass slug. The winding is $\frac{1}{4}$ " long.

similar results. This effect was not noticed in grounded base 432 MHz amplifiers, nor in equivalent grounded grid tube amplifiers. Possibly a 432 MHz neutralized transistor amplifier would not have this problem. The final result was to always use a very weak signal from an antenna or from a signal generator (thru a pad) to align the 432 MHz circuits. This method permits extremely weak signal reception which is the desired result.

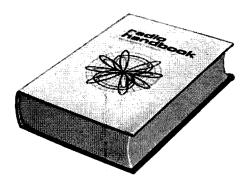

The 220 MHz converter shown in Fig. 3 and in the other photograph was built on a 5 by 2 inch piece of copper plated board. It uses the new TIM10 transistors in grounded emitter circuits without neutralization. The small 1000 pF feedthru capacitors connected to each rf stage emitter were shunted by rather large 820 pF di bypass capacitors. These were connected from emitters to ground across the transistor sockets and act as small shields between tuned circuits as well as aiding in bypassing the emitters to ground. The two rf stages and mixer circuits were run along one side of the board, and the crystal oscillator and diode frequency multiplier on the other side, so the final multiplier coil is near the mixer socket. A low Q broad-band pi network covering 14 to 19 MHz connects the mixer collector to a coax line output to an if receiver which in turn is used to tune the 14 to 19 mc. band. Several of these 5 inch long converter boards were mounted in a 13 x 5 x 3 inch chassis to complete the shielding. All forward gain controls were mounted on a small panel at one end of this chassis. Also included was a small 10 volt zener regulated supply made from a 6.3 volt ac transformer and a diode voltage doubler (full wave) with three 1000 µF 15 volt filter capacitors. The power supply and if coax outputs are switched from different converters by means of a small wafer

The apparent noise figure ranged from 3 to 4 dB in the 220 MHz band subject to errors in the noise generator calibration. This simple converter is somewhat similar to the one described in the June 1966 issue of 73 magazine. Like many letters I've received over the past few decades, "it's just like the one you described in the magazine except it's smaller, uses different parts, and different transistors (or tubes)"—except in this case it works, hi.

Just received word from a TI distributor here in California, that there will be six weeks delay on delivery of more TIM10 transistors. By the time this article is printed, there should be lots of these transistors available and let's hope some of the real hot Motorola EL 229 units on the market also.

of the world-famous RADIO HANDBOOK

- Most comprehensive how-to-build-it source
- Problem-solver for designers & builders

Completely revised and enlarged by William I. Orr, W6SAI. This is the comprehensive communications manual which is the industry standard for electronics engineers, technicans, and advanced radio amateurs. Explains in authoritative detail how to design and build all types of radio communications equipment.

LATEST HOW-TO-BUILD DATA

The new 17th Edition of the RADIO HANDBOOK presents design data on the latest amplifiers, transmitters, receivers, and transceivers. Includes greatly enlarged sections on single-sideband equipment and design, and semiconductors. Gives extended coverage to r-f amplifiers, special vacuum-tube circuits, and computers. All equipment described is of modern design, free of TVI-producing problems.

THOROUGHLY REVISED & UPDATED

Provides a complete understanding of the theory and construction of all modern circuitry, semiconductors, antennas, power supplies; full data on workshop practice, test equipment, radio math and calculations. Includes aspects of the industrial and military electronics fields of special interest to the engineer and advanced amateur. The 17th Edition of the RADIO HANDBOOK provides the broadest coverage in the field—complete information on building and operating a comprehensive variety of highperformance equipment. All data is clearly indexed. 832 pages; $6\frac{1}{2} \times 9\frac{1}{4}$; hardbound. Invaluable for amateurs. electronics engineers. and designers.

A KW With The New Amperex 6KG6

The purpose of this article will be to see what can be done with the new 6KG6. The actual amplifier design is the result of trial and error. It is not supposed to be an example of the latest and most sophisticated technique.

Under the "New Products" heading in one of the recent magazines we spied a brief write up on the Amperex 6KG6. The 34 watts plate dissipation and obvious high voltage capabilities took our eye. So we wrote the Amperex company for spec, then got four 6KG6's for experimental purposes. We are more than pleased with them.

It is assumed that the ham who starts out to home brew a kilowatt is not embarking on his first construction project. So whoever decides to build up some 6KG6's will do it his way with what he can salvage from his junk box. This is what we did.

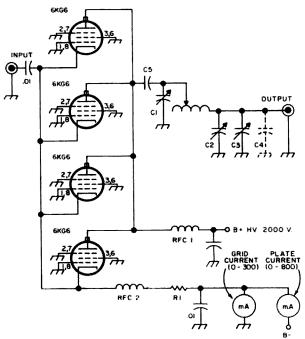

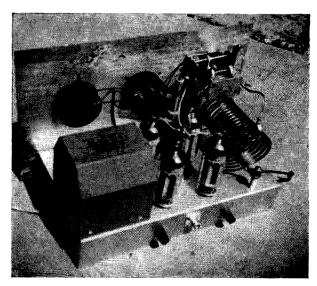

Fig. 1. Schematic of the 6KG6 linear.

We decided to go the grounded grid route by tying all of the grids (control, screen, and suppressor) together and grounding same. As a first try we decided to use an MB 150 National all band tuner in the plate circuit. Don't do it, chum! We wound up on 75 meters tuned about where 40 ought to be and 40 was clear out of the tuning range. It seems that when you tie three grids together and ground them, using four tubes in parallel, you have a plate to ground capacitance on the order of 100 pF. This puts a high frequency limitation on any amplifier and calls for some unusual tank circuit design.

We wound up with the amplifier as shown as per the schematic in Fig. 1. The tank is designed to use minimum C₁ on the higher frequencies due to the plate to ground capacitance being in parallel. This means a turn-byturn experiment. In our case we simply used a battery clip to find the proper tap and then marked the coil. The tank coil should be 20 turns of \%6 inch copper tubing or heavy ground bus copper wire about 2½ inches in diameter. Or-you design your own. The taps could be located by trial and error and then wired into a rotary switch if you like front panel control for all bands. We didn't have a switch. And-what's that double-spaced midget capacitor on top of the tank capacitor? You guessed it—we ran out of copper before we got 20 turns and couldn't quite get on 75 meters and had to outboard a little extra. Some ex-

Bob is the department chairman and an associate professor of electronics at the Oregon Technical Institute. He has a BS in EE and an MA from Washington State University. Many of Bob's 30 articles have appeared in 73.

Back view of the 6KG6 linear good for about a kW input on 80 through 15.

planation is probably in order about the assorted junk we used. C1, the tank capacitor, was liberated from an old command transmitter. The spacing is such that you can't unload the amplifier or it will are over. We always make initial loading adjustments on reduced voltage anyhoo. C₂ and C₃ are 300 pF variables we had on hand. This is still insufficient loading capacitance for the lower frequencies so we outboarded a fixed C4 through a co-ax "T" from the output connector. On 75 meters this amounted to a .001 uF mica and on 40 meters a .0005 µF mica. Strangely enough we found that parasitic suppressor chokes are not necessary with the 6KG6's in this amplifier. Previous experience with 6JB6's led me to put them in. Later we took them out and the amplifier is perfectly stable. RFC1 has to be a good rf choke capable of at least a half amp or maybe an amp. The one used has been on hand a long time and I believe it was made by Johnson. Any good choke that will operate all bands should be ok. This is not a new problem for those who have ever built a shunt fed plate circuit. RFC2 can be a garden variety but must also carry total plate current.

We used an Ohmite choke which measured about 8 microhenries. More would be better. R₁ is a 100 ohm 10 watt wire-wound resistor which is ok for SSB but probably would be better if it were 20 watts. Also if the high voltage is to be left on all of the time 150 or 200 ohms might be better. Our HV is tied to a relay energized by the exciter. We like to have a grid meter but it is not entirely necessary. With the HV turned off you can easily pin a 300 mA meter. Plate meter is in series with the whole stage and the power supply on the B- side.

In its final form the linear performs very well on all bands 80 thru 15. In each case the tank is tapped for as low a value of C₁ as possible. On 15 meters only two turns of the coil are used and the L/C ratio leaves something to be desired; in fact the roving clip lead gets hot. So the output is somewhat reduced. With a Swan 350 as driver the amplifier can be driven to well over 1 kW dc input on all bands. With a 180 or 200 watt PEP rig on 75, 40, or 20 you could get close to 1 kW. We operated at all voltages between 1000 and 2000 volts. At 2000 it is very easy to drive the millameter to 600 mA on speech peaks with the Swan. (We did this into a dummy load, not on the air) There is no flattening. The resting current at 2000 volts is close to 100 mA which makes the plates a cherry red. The plate supply turns off while we are receiving. Total rated dissipation is 132 watts; so we are crowding it in true ham style. Maybe a little greater R₁ would be a good idea. Just how high you can run the HV we don't know but 2000 volts seems like enough.

No doubt the 6KG6 will operate at comparable power as a grounded cathode amplifier and require much less drive. This almost always leads to neutralizing problems and with a pi network this always gets a bit sticky. We have plenty of drive for the grounded grid and it's so much simpler and so much more stable. Anyhoo it looks like the 6KG6 has a promising future.

Drilling Glass

There are several schemes which are used for drilling holes in glass, but most of them are difficult to manage in the home workshop. A simple solution to this problem requires only a dab of wood putty, a teaspoon of kerosene and an old triangular file. First of all, the file is ground down to a point on the end; then it is placed in the drill motor chuck. Place the dab of putty on the glass where the hole is to

be drilled. Fill the crater with kerosene and start drilling with the triangular file bit; drill slowly and keep the bowl in the putty filled with kerosene. To keep the kerosene from splattering, it may be necessary to run the drill motor at a reduced speed. At any rate, this method of drilling glass is much faster and more convenient than any method I have tried yet.

Field Effect Transistor Transconductance Tester

FET's are becoming more and more popular with hams. Here's a simple tester for them.

With the recent advances made in the manufacture of field effect transistors (FET's), the resultant price reductions and their extended usage by industry, greater and greater quantities of FET's have been dumped on the surplus market. Many of these surplus FET's are perfectly good, but some are defective; this isn't usually the fault of the dealer, he just doesn't have an easy way to check them.

Unfortunately, you can't check out an FET with an ohmmeter like you can a conventional junction transistor; some other method must be used. The most obvious approach is to use a transconductance tester similar to that used in testing vacuum tubes. However, since the FET requires no filament power and a relatively low value of B+, the entire test unit may be made quite compact and portable.

You will remember from your school days that the transconductance of a vacuum tube was the ratio of the change in plate current to the change in grid voltage with the plate voltage held constant. For the field effect transistor, the definition is almost the same; just change the name of the respective elec-

The FET transconductance tester. The pushto-test switch is a Grayhill model 35-1; the transistor test socket a Pomona TS-187.

trodes and you have it: FET transconductance is the ratio of the change in drain current to the change in gate voltage with the drain voltage held constant. In practice all you have to do is apply the proper bias voltages to the FET, apply a small measured amount of gate drive voltage and measure the amount of resultant ac drain current. Then the transconductance in mhos¹ may be calculated from the following formula:

$$g_m = \frac{I_d}{E_g}$$

 $\begin{array}{rcl} \mbox{Where:} & \mbox{g_m} & = & \mbox{Transconductance in mhos} \\ & \mbox{I_d} & = & \mbox{Change in drain current} \\ & \mbox{E_g} & = & \mbox{Change in gate voltage} \end{array}$

When the drain and gate measurements are given respectively in microamperes and volts, the transductance is given in millionths of a mho or micromhos, the conventional term.

The FET transconductance tester described here combines the essential necessities with some operating conveniences that make it more versatile for all around FET tests. Basically, a small amount of 1000 Hz voltage is applied to the gate of the FET; the resultant 1000 Hz drain current is rectified by the full wave diode bridge and measured on the meter. The bridge circuit is capacitively coupled to the drain of the FET so the dc supply component will not affect the meter reading. Likewise, a large choke is included in dc supply lead to prevent the 1000 Hz signal from being bypassed to ground through the power supply.

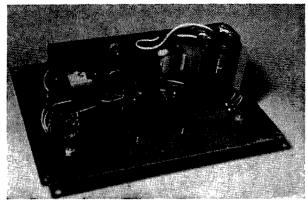

A potentiometer is connected in the gate bias circuit so that the gate bias may be varied from zero to nine volts. This is very helpful in determining the effect of various bias levels and in measuring the gate-cutoff or

¹ The new term for mho is siemens. Unlike hertz, siemens is not widely used yet.

pinchoff voltage of the device. Since the polarity of the dc supply voltage may be conveniently switched from the front panel, this unit will accommodate either P- or N-channel FET's. In addition, two ranges of transconductance, 2000 and 20,000 µmhos, are provided by placing appropriate shunts across the meter.

The entire transconductance tester is built on a 415/16 by 61/16 inch aluminum panel laid out as shown in Fig. 2. After the unit is completed, this panel is mounted in a standard bakelite instrument box. All of the active circuitry, including the 1 kHz audio oscillator, is laid out on a piece of perforated Vero board 1% inches wide by 4% inches long. This board is mounted to the front panel with an aluminum angle bracket. No screws are used to hold this bracket to the panel; the battery polarity switch, push to test button and bias poteniometer do the job. There is no crowding of the board. The layout is not at all critical and any convenient arrangement is suitable. The two batteries are mounted on one side of the unit in an aluminum bracket which is epoxied to the Vero board.

The toughest part of the whole construction lies in the meter shunts. The meter used in the author's tester, a 50 microampere unit from Radio Shack, required two shunts, one for 100 microamperes and one for one milliampere full scale. These currents correspond respectively to 2000 and 20,000 micromhos full scale. The required values were calculated from the standard formula and then made up

Interior of the transconductance tester. The 1000 Hz oscillator is mounted in the upper left hand corner of the Varo board. The batteries are installed in a metal clip on the far right.

from standard carbon composition resistors. In each case a carbon resistor with a resistance value *less* than the desired shunt resistance was chosen. Then a small amount of the resistor was filed away with a rat-tail file until the resistance was raised to the desired value. Initial resistance checks were made with an ohmmeter; final tests were made by comparing the shunted meter to an accurate VOM. Except for the nonlinearities which seem to be inherent in low cost meters, the results have been encouraging.

After the shunt resistors are completed, they should be completely covered by a coat of epoxy cement. Since the protective composition cover is destroyed during the filing, the epoxy coating will prevent the ingress of moisture. Moisture will change the value of

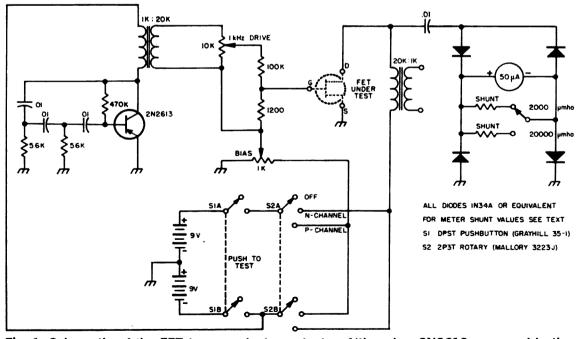

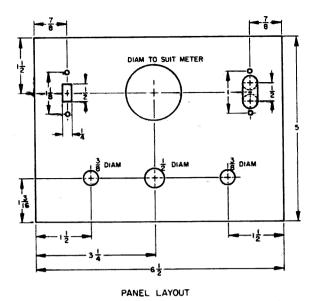

Fig. 1. Schematic of the FET transconductance tester. Although a 2N2613 was used in the 1000 Hz oscillator in the original model of this tester, almost any high gain transistor may be used in this circuit.

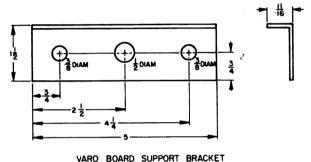

Fig. 2. Panel layout and Varo board mounting bracket.

the shunt resistance and affect the accuracy of the meter.

Although it is not strictly necessary to duplicate the parts used in the author's transconductance tester, it does help in acquiring the necessary components. All of the parts are available from the large mail order houses such as Allied, Lafayette or Newark. This is a help because several of the parts, notably the 2PST pushbutton switch, are not normally available through neighborhood distributors. The 50 microampere meter was chosen because of its modern appearance, availability (locally) and low cost. However, any small instrument with a sensitivity of 50 or 100 microamperes would be suitable. A 100 microampere meter would have the additional advantage of requiring only one shunt (for 20,000 micromhos full scale).

After the tester is completed, there are several adjustments which must be made before plugging in an FET. First of all, connect a set of ear phones across the secondary of the transformer in the output of the audio oscillator. When the push to test button is depressed, a 1000 Hz note should be heard. Switching from P-channel to N-channel should have no effect on the tone. Next, measure the amount

of 1000 Hz signal available on the high end of the drive potentiometer with a VTVM; 8 volts RMS is about right. Now, place the VTVM test probe on the wiper of the driver pot and adjust for 1 volt RMS. This will put 100 millivolts of 1000 Hz drive on the gate of the FET being tested.

Now connect the dc probe of the VTVM to the gate connection on the test socket and adjust the bias potentiometer for 5 volts. Loosen the knob and set it opposite the 5 on the bias scale. If you don't have a VTVM for these initial setups, don't worry about it; a good VOM will work just about as well.

The discerning readers among you have probably figured out that 100 millivolts of drive (0.1 volt) and 100 microamperes of drain current do not add up to 2000 micromhos... You're right, they don't-1000 micromhos is more like it. That is, if all of the 1000 Hz drain current were flowing through the bridge. However, in this circuit, the 1000 Hz drain current divides just about equally between the audio choke in the drain power supply lead and the capacitively coupled meter circuit. So, twice as much drive must be applied to obtain accurate readings. would be circumvented by using a larger value of coupling capacitance. However, when the push to test button is depressed, there is a large surge of current through the capacitor as it charges through the diode bridge. In the original model of this tester, the large voltage spike from the charging of a 0.47 coupling capacitor (since replaced by the 0.01 µF) destroyed a couple of \$13 FET's.

Now you're all set to test those new FET's. Set the P- or N-channel selector switch, put the meter on 20,000 micromhos, and set the bias pot to zero. Push the test button—if the FET is a good one, the meter should swing up scale. If it doesn't, try adjusting the amount of gate bias. If you still don't get a reading, change the setting of the P- and N-channel switch; the device may have been mismarked.

When a good FET is being tested, note that the transconductance varies with the amount of gate bias voltage. Normally, as the bias is increased from zero, the transconductance will increase and then decrease. The point where it starts to decrease after reaching a peak approximates the gate cutoff-voltage or pinchoff voltage. This is directly analogous to the grid-cutoff voltage in a vacuum tube. With knowledge of the cutoff voltage and transconductance curve, it becomes quite easy to optimally bias the device in a circuit. Remember though that these are the characteristics of the FET with a 9 volt drain supply; other supply volt-

ages will change the operating characteristics slightly. However, this does not negate the usefulness of the transconductance tester; on my bench it has proven to be extremely useful in determining bias levels and in sorting out defective FET's.

Afterthoughts

How would you like to measure the transconductance of conventional junction transistors? In some transistor circuit design transconductance is a very useful characteristic. This can be very easily done by the addition of one SPDT switch connected in the gate (base) supply lead as shown in Fig. 3. In the FET position the gate voltage is oppositely polarized from the drain supply voltage. In the junction transistor mode the base supply voltage has the same polarity as the collector supply. Now the transconductance tester will measure the transconductance of PNP devices when in the P-channel position, and NPN devices when in the N-channel configuration.

When running transconductance tests on junction transistors, handle the bias control very carefully. Most transistors will be destroyed if the base to emitter voltage is more than 4 or 5 volts; some with considerably less. Since the emitter of the transistor is grounded in this test circuit, always start the test with the bias pot on zero.

The additional capability afforded by this one switch has the additional advantage of discriminating between FET's and junction transistors. It's quite easy to tell whether that newly acquired FET is really an FET or a mismarked (or misadvertised) junction transistor!

. . . WIDTY

Climbing the Novice Ladder

Part II: Joe Starts A Home-Brew Project

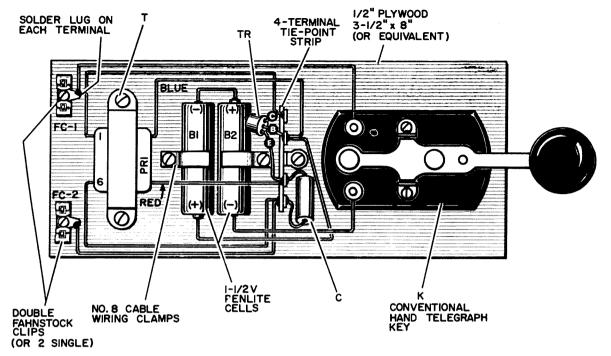

On the Saturday morning following his initial visit with Larry to the ham shack of ol' timer Dwight Mansfield, or 'FN' as he preferred to be labelled, Joe hopped on his Honda and again headed out to the basement shop. Today was the day he was to build a code practice oscillator under FN's guidance, as his initiation into amateur radio 'home-brew' construction. After greeting Joe heartily, FN immediately launched into a bit of preliminary explanation. "I've got everything here in this little tray Joe, all cadged from my junk box, so we're ready to go. While a little piece of gear like this could be mounted in a neat little metal cabinet and marked with decal lettering. it's hardly worth it. A CPO, which is what the hams call a code practice oscillator, is not considered a permanent piece of station equipment. You'll probably use it for only a few months at most and then discard it for its original purpose, saving the parts however to start your own junk box for future projects.

Here's the schematic of the code practice oscillator (CPO) shown in pictorial form above.

So let's mount it 'bread-board' style on a little wooden base. That way you'll find it easy to work on and you can turn out a neat little job in a very short time. I picked up a little piece of scrap board the other evening and gave it a coat of paint to take away the 'raw' look. It's nice and dry now and you can go right to work on it. Your first chore will be to mount the few parts and I've made a rough layout sketch for you to follow. You'll find all the tools you'll need right here on my tool board so go to it; I'll be right outside mowing the lawn if you run into anything that puzzles you; call me when you're through mounting the parts."

Thanking FN, Joe turned to the bench and picking the parts from the salvaged TV dinner tray, identified them one by one from the sketch FN had left him. "Gee," he thought. "that TV tray is a neat idea for keeping the parts right in front of you where you can easily find 'em. We use those TV dinners at home; I'll get Mom to save me the trays." Taking up the transformer which appeared to offer a good starting point, Joe reached for a screw-driver nested with others in an orderly rack on the tool board, positioned and marked the transformer placement on the baseboard in the position shown on the sketch. With a handy prick punch the screw holes were started and with a couple of #6x½" round head wood screws from one of the tray compartments, the transformer was soon mounted. The pen light batteries which would power the CPO, seemed like the next logical items to mount. FN's sketch called for a couple of

Pictorial diagram of the simple code practice oscillator that Judy and Joe built under FN's supervision. It's shown half size.

cable wiring clamps for this and sure enough, there were two in the tray. Another pair of wood screws and presto . . . the batteries were in place.

Joe had just selected the tie-point terminal strip to mount next and was positioning it on the baseboard when the door opened and he was a bit taken aback when not FN, but an attractive young lady of about his own age walked in! She put him at ease at once in the easy familiarity of today's teen-agers; "Hi . . . you must be Joe Blake . . . I'm Judy Mansfield, FN's granddaughter," adding as she wrinkled her pert little nose, "I call him Gramps though. He told me I'd find you here and thought maybe I could give you a hand."

"Well hi" Joe replied, "are you a ham too?"
"No" she said, "not yet. Gramps has been giving me the old needle for some time now to learn the code and join the fun but I couldn't get too much interested in learning by myself . . . it looked like a dreary job. Gramps says you're about to start studying for your ham ticket; maybe we could work together."

"Wow," Joe thought, "she's really neat; this sounds like a break!" Aloud he said, "Sure Judy . . . it'd be a lot more fun learning that way; you wanna help me finish this little oscillator?"

"Why not Joe . . . Gramps has used words like that lots of times . . . maybe now I can find out what they mean!"

Having established a common bond through

a mutual interest (perhaps not entirely electronic!), Joe proceeded to explain what little he had so far accomplished. "Look Judy; here's what we have to do" he continued. "Mount these other pieces on the board like I did with the other two. Why don't you do the tiepoint and the key . . . I'll show you how I did the others." Judy proved pretty adept with the prick punch and screw driver and did her part in short order, prompting Joe to say, "Gee Judy . . . you handle tools like an old hand . . . ever use any before?"

"Lots of times Joe; I've helped Dad with his cabinet-making, putting on little hinges and things like that. Once I spent quite a bit of time right here helping Gramps put a hi-fi kit together . . . it's kinda fun." With that Joe was sure he'd found a kindred spirit; now ham radio really was for him!

All that was now left of the mechanical assembly was mounting the little clips which would serve as binding posts for the phones. These were labelled "Fahnestock clips" on FN's sketch and Joe had them and their accompanying solder lugs mounted in place in short order. "Well, I guess we're ready to wire the thing Judy; I'd better let your Gramps know" and so saying Joe went to the door and called, "All parts mounted FN . . . what next?"

From around the corner of the house FN replied, "All set eh? I'll be with you in a minute." As he came through the door he said, "Well I see you kids got together. I thought you might find it a little more pleasant to work

together as long as you both have an interest in ham radio. You'll find Judy pretty handy with a screw driver and a pair of pliers Joe . . . look out she don't outstrip you in homebrewing."

Laughingly Joe replied, "Yeah; she sure takes hold of a tool like a born mechanic."

Connecting the parts looked to be not too difficult; Joe had done more than a little soldering in his school physics class and in experimental electrical projects at home. Judy had somewhat less experience although FN had shown her the basic principles of soldering and she had made a few connections for him from time to time; both she and Joe were therefore adequately equipped for this little project.

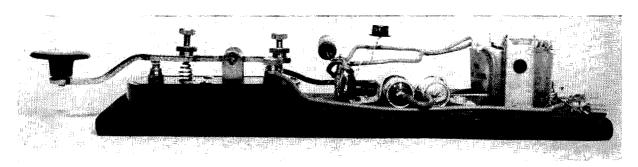

FN handed them another rough sketch which showed the wiring in pictorial form. He then explained, "When you've had a bit of experience in building electronic gear you won't need these wiring 'pictures' to work from. You'll use a 'schematic diagram' which uses symbols to represent the various parts and simple single lines to show the connections. When you're through with this job I'll draw you a schematic circuit on the back of this sketch and you can compare them; all good ham constructors use schematics just like the professionals do. I'm going to give you just one tip before you start wiring. We're using one of the little transistors for the oscillating element here . . . you know about transistors from your pocket radios. We could use a vacuum tube but it would take a more intricate power supply, would cost more, complicate the building and gain . . . nothing! We could even use a common, ordinary buzzer like you probably have at your back door. Either of these would make up into a useable code practice set. We've ignored the tube for reasons I've explained . . . buzzers generally have an unpleasant raspy sound and often change pitch while you're sending; this throws you and upsets your practice. The transistor oscillator is stable, reliable, produces a nice tone and is easy to build but it is susceptible to excess heat. When you solder it's three wires to the tie-point strip, be sure and hold each wire close to where you are going to solder, with the long nose pliers and do the soldering as rapidly as possible but be sure it's a solid connection . . . I'll check it when you're through. Besides holding the wire in place for you, the pliers will serve as what we call a 'heat sink' which will draw the heat to the pliers rather than having it run up the wire to the transistor body. That's it kids, I'll go finish mowing the lawn."

The young people turned back to the bench and while Joe picked up and examined the transistor, Judy suggested, "Joe, why don't we do the transistor *first*; we'll get it out of the way then . . . the rest looks pretty easy."

"OK" Joe replied as he plugged in the soldering iron; "you wanna put on the first wire and I'll do the next?"

"Oh, no Joe . . . you put on the first two while I watch vou . . . that way I'll catch on and then I'll do the last one."

With that, Joe picked up the long nose pliers and carefully made a little hook in one of the tiny wires protruding from the transistor body. He hooked this into terminal lug #1 on the tie-point strip and squeezed the hook closed with the pliers. The quick heating iron was ready now so, with a short length of solder wire and holding the connecting wire close to the terminal with the pliers, Joe completed the termination. Previous experience in soldering had taught him to always apply the heated tip of the iron directly to the terminal; never to the solder. When the terminal itself had absorbed sufficient heat to melt the solder, he carefully placed the end of the solder wire against the terminal at the point where the little wire hooked into it, keeping his iron in place against the back of the terminal until a small amount of solder had liquefied and run down over the face of the terminal, burying the wire hook in the molten solder. He then carefully removed the iron so that the cooling solder was not disturbed. He then repeated the operation using the second wire from the

Side view of the code practice oscillator built by Judy and Joe.

transistor and after cradling the iron in its rest, handed the pliers to Judy. As she had absorbedly followed the process both times that Joe had accomplished it, she then proceeded to repeat his performance in commendable style; both were satisfied that they had the transistor licked. As Joe unplugged the iron to keep from cooking the tip, the door opened and FN appeared with a couple of bottles of Coke and a bowl of potato chips. "Time out for a Coke break, kids; you ready for it?" Both replied in chorus, "You said it!"

FN then produced a thermos of hot coffee from the confines of his shack, poured himself a cup and while giving it a minute to cool a bit, examined the transistor wiring. "Good," was his pronouncement, "you've got nice shiny joints proving that they are soldered with metal, not 'resin' joints held together with the flux from the solder wire. A resin joint won't conduct electricity and your project won't work. A cold solder joint, produced when you don't heat the connection sufficiently to make the solder flow freely, is bound to be a troublemaker too. You can recognize a cold joint as the solder won't be smooth and shiny but will appear dull and grainy. You do have a bit of resin residue on the surface of the solder though. While it does no harm, it makes the joint appear unfinished. You can easily remove this by scraping lightly with the point of a knife blade, followed by wiping it with a cloth dipped in alcohol or shellac thinner. There's some thinner in that upper cabinet . . . rags in the metal waste can under the bench . . . want to clean it up Judy?"

FN rinsed his cup at the laundry tub faucet, the empty Coke bottles were dropped back in the carrier and Judy proceeded to clean the resin residue from the tie-strip terminals. finding it surprisingly easy and quick and resulting in a more workmanlike appearance to the soldered terminals. By then, FN had gone out to clip the hedge after leaving them several scrap lengths of hook-up wire with which to complete the wiring. Removing the insulation from the wire ends, commonly referred to as skinning and preparing the wire for connection by tinning or coating with a thin film of solder, was duck soup for Joe after having accomplished such operations both at school and at home. He soon had Judy cutting the wire lengths he needed, skinning the ends and passing them to him to tin and solder in place. Working together like this the job went fast and in half an hour Joe unplugged the iron and said, "Well, Judy, I think we've got it made . . . it should work now; wanta call your Gramps?"

FN gave the completed project a careful

inspection; almost at once he said, "A nice looking job kids but it'll never work!"

With some trepidation Joe asked, "What's wrong FN?" while Judy shot her Gramps a questioning look.

"Look here Joe, you've left out one all-important wire . . . from the key to the battery!"

A quick look and with a somewhat crestfallen look, Joe acknowledged the point . . . "Don't know how I missed it FN, but I sure enough did; cut me a 4" hunk of wire, will you Judy?" and he plugged the iron back in.

Entering his shack, FN tossed back over his shoulder, "It's the little things Joe that cause big troubles; can't be too careful in checking even the most minor projects."

As Joe completed correcting the omission, FN came from the shack carrying a pair of headphone receivers. Another quick check-over convinced him that the wiring was now complete and connections solidly made. He inserted the tips of the headphone cord into the Fahnestock clips and manipulated the hand key several times. His expression told the story although both kids could faintly hear the pleasing musical tone the oscillator made, even though the phones were tightly fitted over FN's ears. A relieved sigh from Judy and a broad grin from Joe met FN's pronouncement; "Well done, me hearties . . . you've got yourselves a workable code practice oscillator; now all you have to do is to learn to use it and use it p-l-e-n-t-y! Let's talk about that next.'

Swinging a somewhat battered old cot out from a gloomy corner FN said, "My thinkin' couch . . . you can sit here . . . I'll get my chair from the shack." With all comfortably seated, FN stoked his pipe, lit it and, when drawing to his satisfaction, offered some sage advice; "Joe, Judy lives down the road a piece toward town . . . about three miles closer than I do: that puts you two about 4 miles apart. Now if you're going to get in a reasonable amount of code practice together, you're going to have to arrange pretty frequent sessions between vou. No need to come way out here two or three times a week; glad to have you visit anytime but for code practice you'll do better in a more familiar environment. Joe, you've got a motor bike . . . 4 miles is just a hop, skip and jump for you. Why don't you stop at Judy's place today on your way home, meet her Ma and Pa and work out something among you that will get you kids together for an hour or so two or three times a week? The fall term of school won't start for about five more weeks so you should be able to get in some pretty good licks meanwhile."

"Now here's another little pitch," FN continued, "you've got one CPO between you and

! ADD PUNCH AND CLARITY TO YOUR SIGNAL!

- INSTANTANEOUS LIMITING ACTION
- NO APPRECIABLE DISTORTION
- COMPLETELY COMPATIBLE WITH SSB
- TALK POWER GAIN AT LEAST 10db
- OPTIMUM FREQUENCY RESPONSE
- INSTALLS IN MICROPHONE LEAD
- ALL SOLID STATE PRINTED CIRCUITRY

NEW

COMDEL SPEECH PROCESSOR MODEL CSP 11

A prototype of the CSP 11 has proved itself an effective communication aid on the amateur bands over several years. Its prominent feature is the instantaneous limiting action without the harmonic distortion which often makes the use of conventional speech clippers marginal, particularly with SSB transmitters. Designed for relatively insensitive high Z microphones—a gain control is provided—the unit will enhance the intelligibility of voice signals considerably under difficult conditions. "MIL" design and construction is employed throughout for high reliability and long life. Power is obtained from internal batteries (6 "D" cells—life exceeds 300 hours) or external source. Free brochure will be sent on request.

PRICE: \$111.00 POST PAID IN U.S.A. (Mass. residents add 3% tax)

no headphones . . ."

Joe broke in here with, "I've got a pair of phones, FN, I've done a bit of short wave listening from time to time though I never got really excited about it like I am with ham radio. My phones are marked "2000 ohms"... will they do?"

"Splendid" replied FN, "I have this extra pair of phones which I'll loan to Judy. Now maybe you wonder why two pair of phones with only one oscillator and one key. I'll tell you; I've got a little CPO and several keys left over from my adult education classes at the High School a few years ago; I'll also loan Judy the CPO and a key. That way you'll each have practice equipment at home so you can practice sending to yourselves at odd moments between your get-togethers; you'll gain confidence in handling the key and familiarize vourselves with character formation that way. When you get together, have both pair of phones with you; that's why the double Fahnestock clips on the CPO you just built; you can clip two pair of phones into them then. The CPO I'll loan Judy is fixed the same way so equipment-wise, you're all set now. From here on out it's your baby for the next few weeks. Come out here on Saturday mornings when you can and bring one CPO and I'll check your progress; no need to bring the phones . . . we'll use mine from the shack for the test sessions. Joe, you take this little CPO you just built with you and git fer home now; take this little book too; it will give you a bit of dope on proper grip of the key, character formation and the like; swap the book back and forth between you. I've got to run down to your place this afternoon, Judy, to see your Pa and I'll bring my CPO, a pair of phones and a key for you. S-o-o-o, that's for now kids and let's see what you can do with the code in the next few weeks."

Chorusing their profuse thanks, Judy mounted her bike and took off, Joe leisurely trailing behind on his Honda.

Next month: FN checks Judy and Joe on their progress and starts them on their technical studies. . . . W70E

Parts List

		Parts List
2	FC-1, 2	Double Fahnestock clips (or 4 singles)
1	T	Universal output transformer (Knight 54A20323)
2	B-1, B-2	1.5 volt penlite cells
1	Tr	2N107, HEP250, GE2, SK3003 or almost any other low power PNP transistor
1	\mathbf{c}	.25 μF paper capacitor
1	K	Conventional hand telegraph key
1	TS	4-terminal tie-point strip
2	CL-1, 2	#8 cable wiring clamps
1	RR	14" plywood base-board, 314 x 8"

Bill Johnson W6MUR 9372 Hillview Road Anaheim, California 92804 Illustrations by Wayne Pierce K3SUK

Bill is a consulting engineer with a BSEE from the University of California, graduate work in EE and undergraduate work in law. He's been a ham since 1935, and enjoys DXing.

The QRZ Machine

Insula Nuevo° was the beginning of a long string of triumphs for Jules Silvergold III, W2BUKS. There were St. Ginsburg's Rock, Low Tide Shoal, Ebony Sandbar, and several more that he alone could claim. Jules even received the Elby Jaye Award at a special Texas ceremony for removing so many hazards to navigation as his new countries vanished by the push of a button on his departure. Jules was the unquestioned DX champion, but he found this a strangely lonely experience, for once the other HRAs°° realized there could be no top for them, they rediscovered the fun of the game. Jules traveled alone in a polite but aloof fraternity.

But Jules had other troubles too. Grand-father's estate proved not inexhaustible; moth-balled Liberty ships got scarce, and the cost of rock, barges, and even TNT had soared over the years. The IRS had denied him a deduction for the helicopter, too. Jules' father had long since put his well-heeled foot down and for the first time in his life, Jules was face to face with economic reality. A crisis was approaching.

On his flight back from Amuck Islet Jules stopped in at the Fresno DX conference to hear about the latest exploits of each of the 27 professional travelers and their foundations. Jules had been at Fresno once before, back in 1966 when Foundation Fever first started on its epidemic way. He had regarded it then as a sort of prostitution of the amateur service, but after reviewing the annual balance sheets for many years, Jules now thought differently. In his present predicament there just might be something to this, after all.

• • Honor Roll Addicts

^{*} See QST, February, 1965, p. 96

So Jules listened carefully while the 27 speakers paraded to the Fresno rostrum, showed their slides of the native girls and the erections of stubs and towers, and played recordings of the pile-ups. One of the highlights of the meeting was the recording of the time five DXpeditions were all on at the same time and the piles drifted together on 14025. The speakers had to borrow each other's recordings to find out who worked whom.

Clearly, thought Jules, some improvements were called for. With 97,600 active DX men by actual Honor Roll count, there were well over 1000 for every kHz that remained of the 20-meter band after the Canberra Conference in 1968. (The broadcasters had seen the balance sheets too, and had won some major concessions.) And the Fresno speakers had a lot to complain about. Tactics were indeed getting a bit rough, and more efficiency was clearly called for. One speaker even discarded his carefully prepared talk to editorialize and harangue the convention on this very subject.

And then Jules spotted an old Harvard friend, one of the electronics types who had designed the big 14050 computer used for the first Venus trip. Ferrite Manibit was his name, a scholarly looking bright-eyed chap who, though now graying slightly at the temples and balding on top, was still as bright as ever and was well planted now in W6. Jules invited him up to his 18th floor suite after the dinner meeting for a few drinks and a little private talk.

Jules checked the suite for bugs and swore Ferrite to secrecy on what he was about to say. He told Ferrite about his dollar problems and how even the helicopter was now mortgaged to the hilt. Jules then outlined his plan.

"The real problem is that you simply can't work 97,600 guys in less than 40 days, no matter how hard you try," said Jules. "What every one of these 27 chaps has said is that they need more efficiency. Now I've been thinking. How much memory can you put in the size of a portable typewriter now?"

"Oh, about 4 megabits, I guess," Ferrite replied. "We worked up one computer for the Pluto shot that had about that in it. Of course, we have to go fully integrated to be able to do any processing in that space. Why?"

"Well, what I have in mind is a sort of data processor. I can still afford to fill in one or two more shoals but then I'm through. I thought this time I'd like to work the rest of the boys instead of just W2BUKS. It would improve my popularity, I think, and after looking at these Foundation balance sheets I think it could solve my other problems too. What's the going rate on QSO's, anyhow?"

"Oh, some of them have gone for as little as \$10, what with inflation and all. It depends on whether it's a new one," said Ferrite.

"Well that's a good round figure, and we can convert it to Sterling or Rubles or whatever for the boys abroad. Now what I want is for you to put together a little data processor for me with a keyboard on it, so I can type in the call and all the pertinent data on each contributor before I leave. And I want some recognition circuits in there to unscramble the CW out of the pile and check the call against the master file. If he's paid, it sends a standard report-let's say 579 for the minimum or if he goes to \$25 he gets 599-and then automatically logs the contact on tape. While this is going on, I want it to send QRZ and key the other rig. Then for QSL's all I have to do is play the tape back home and they're printed, stamped and addressed. Think you can do it?"

"Jules, I think you've got something there!" Ferrite's mental abacus was flicking through \$15 average, times 97,600, times 2 for the second contact, less trip expense, payoff to

customs and licensing officials, etc. "I don't see any real technical problem here at all, and I'll tell you what I'll do. I'll design it and build it for you for 50% of the trip net. How's that?" he said.

Jules was shocked. "50%!! Are you out of your mind? 25%!"

"Well I don't ordinarily work on a contingent fee at all, but I'll go 35%, and that's it."

"You have a deal," said Jules. "You get it to me in Long Island by June I and I'll do the rest."

"Just be sure you work me too," said Ferrite. So the QRZ machine was built, and worked beyond Jules' wildest expectations. Ferrite had thought up a few more convenient features, like being able to take several calls at once.

He figured to make at least 1000 QSOs per hour.

Meanwhile, Jules dusted off his Harvard class notes and went to work. Full page ads, brochures and application blanks, mass mailings to the HRAs, and all the rest—it was a publicity campaign never seen before. The applications and \$10 bills came pouring in, for contacts to be made with Volcano Spit. Jules called his foundation the SubOceanic Geological and Geographic Institute (SOGGI) and won the coveted IRS tax exemption on the basis of his stated purpose of research on how to stimulate suboceanic eruptions to create temporary islands.

The expedition itself was routine, at least for Jules. His solid-state equipment easily fitted into the helicopter, and of course his contractors and shipping people were old hands now in manufacturing islands. Jules kept everybody posted through regular QST broadcasts taped from his home station in Long Island. His time of arrival was pin-pointed to the second, and everyone synchronized their watches and got off work in plenty of time. The word was out on procedure—the W6's would come first (Ferrite had insisted on this). then the W2's, and then, in deference to Texas, would come the W5's. Propagation was all worked out so there would be no problem with the signals.

The QRZ machine performed admirably. Once or twice Jules had to type in the call when the check stop light came on, but except for that the predicted 1000 QSOs per hour were easily achieved. While Jules relaxed, the QRZ machine did the work, two bands at once with two rigs per band. When some of the free loaders showed up, the machine would reject their calls as unacceptable and come back QRZ. Those it recognized were automatically logged, and the standard reply made. All in all, the Volcano Spit operation was by far the most efficient and successful of any DXpedition ever. Four days after arriving, 91,382 HRAs had their new country, and Jules' Honor Roll lead was reduced by one. Jules packed up and returned to Long Island.

But once again ancient and outmoded laws took over. Profit-motivated competition, pretty well discredited over the years, emerged. The 27 regular foundations convened an emergency meeting of the DXpedition Foundation Association and took corrective action.

So Jules never had to make that second trip and decrease his Honor Roll lead one more. Ferrite Manibit retired in Palm Springs luxury. QRZ Machines, Inc., was doing an island-office business.

A Simple Converter for 70 cm TV

This three-transistor converter furnishes a quick way to receive ham television signals on 440 MHz.

Here is a simple converter for the 430-450 MHz ham TV band. The two rf stages are conventional quarter-wave trough-line circuits. They possess very high Q so the amplifiers are rather narrow—at least for TV. The mixer-cscillator also uses trough-line circuits.

The AF139 transistor (U. S. equivalent is Amperex 2N3399) has a collector capacitance of only 1 pF and a comparatively high collector resistance so it loads the high Q circuits very little. The converter has fairly high resistance to overloading and spurious signals in spite of the high sensitivity of the converter. Each rf stage has a gain of about 10 to 12 dB.

The tap point on the input trough line is set for a 52-ohm antenna. If you want to use a 75-ohm antenna, the tap should be moved a few millimeters up from the grounded side.

Emitter current of the AF139 should be set at about 1.5 mA for lowest noise.

It is advisable to use button mica or other UHF capacitors for coupling and decoupling. Disc ceramics can be used if they are modified slightly. Heat one side of the capacitor to crack off the ceramic and unsolder one lead. Then place the bare, tinned side of the capacitor against a tinned part of the chassis while heating the chassis from the other side. This makes a very good UHF capacitor, though you may break a few capacitors doing it.

The third transistor in the converter is a self-oscillating mixer. It is stable enough for wideband TV.

A voltage variation of 2 volts causes a frequency drift of only 100-125 kHz (a TV signal is about 4.5 MHz wide). Even a rise in ambient temperature from room temperature to 150° F makes the oscillator drift no more than 80 kHz.

The 0.8 pF capacitor between the emitter and collector maintains oscillation. The inductor L5 compensates the capacitive part of the input impedance, and moreover, functions as a low impedance path for the *if* signal and the emitter current. The collector current of the oscillator-mixer is 4.5 mA.

The if signal obtained after the mixing process is filtered out by L6 and the 6 pF capacitor and fed by a link to the input of a TV receiver tuned to channel 2 (54-60 MHz in the U.S.). L6 is damped with a 2.7 k Ω resistor to get sufficient bandwidth.

L6 and L7 are housed in metal shields on top of the chassis. The coaxial connectors were spaced off the chassis a little to prevent their interfering with the quarter wave lines.

You can silver-plate the chassis and lines for the utmost in reception.

Good luck with the construction and reception.

. . . PAØBVO

This article originally appeared in the February 1966 issue of CQ-PA published in the Netherlands. It was translated by Jos. Stierhout PAØVDZ.

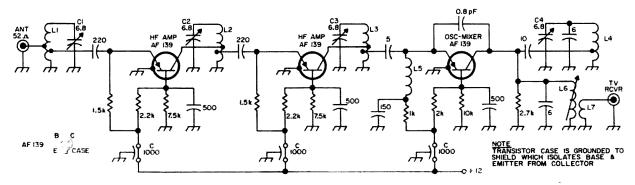

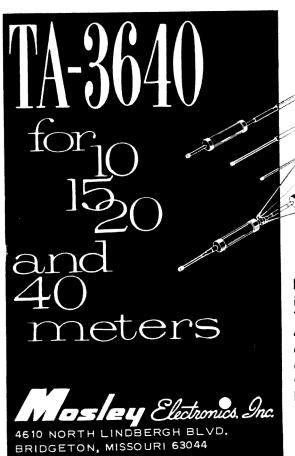

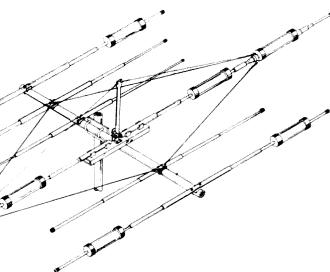

Fig. 1. Schematic of the simple 440 MHz converter for ham TV. L1-L4 are quarter-wave trough lines, 5 mm ($^{1}\!\!/_{4}$ ") in diameter and 68 mm (2-11/16") long. L5 is 3 turns number 18 7 mm (5/16") in diameter. L6 is 7 turns number 18 on a 5/16" form and L7 is 3 turns on it.

Put your signal where it counts. Use the ultimate in Ham beams - - - the Mosley TA-36 with Kit TA-40KR added to radiating element. Employs 4 operating elements on 10 meters, 3 operating elements on 15 meters, 3 operating elements on 20 meters. SWR is 1.5/1 or better at resonant frequencies over all 4 bands. Constructed of heavy-wall aluminum for maximum strength. Rated for full power.

Write for detailed specifications and performance data on the Mosley TA-3640.

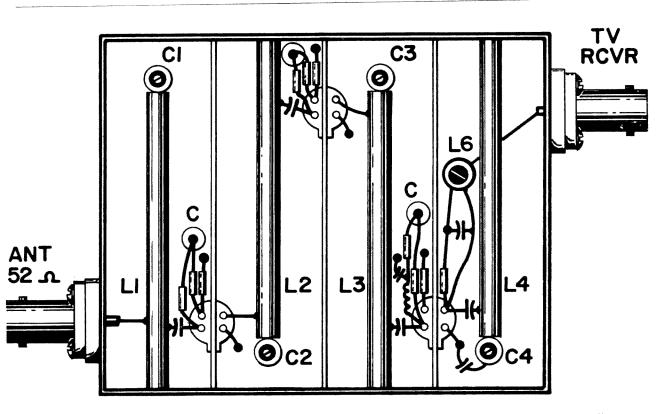

Fig. 2. Full size layout of the ham TV converter. This view is from the underside. The walls of the converter are 30 mm ($1\frac{1}{4}$ inches) high.

Silect Six Meter Converter

This simple and inexpensive six meter converter uses low-cost Texas Instruments plastic-cased Silect transistors. The rf stage is an FET, too.

Have you heard about the new Texas Instruments economy line transistors? TI calls them "Silect" transistors and they give excellent performance at low prices.

I recently attended a transistor seminar sponsored by TI in Dallas. Among the topics and devices discussed were a number of the Silectline transistors, including the TIS34 N-channel VHF epitaxial planar silicon field effect transistor. This transistor, which is a low-cost version of the excellent 2N3823, has been written up before in two 73 articles: "RF Applications of N-Channel FET's" by WA5KLY in the May 73 and "A Low-Cost FET Two Meter Converter" by K6HMO in the October 73. The TIS34 is ideal for VHF mixer and amplifier service. It has a low noise figure and high, high frequency figure of merit. Cross modulation is minimized by its square law transfer characteristics. This transistor is used as the rf amplifier in converter.

The TI409 transistor, which wasn't discussed at the seminar, is an excellent NPN planar silicon transistor for general use. It costs 75¢, not a bad price for a 500 MHz, 200 mW transistor. Both transistors are encased in inexpension.

sive plastic packages. Note that the leads of the TI409 are a bit different from most transistors.

Total power consumption is 2.5 mA at 12 volts.

This converter is similar in many ways to previously-described converters except for the FET rf amplifier. I couldn't find any FET rf circuits when I was starting to build this converter, so I decided to come as close as possible to tube circuits. The gate (grid) resistor was varied from 470 k Ω to 3.9 M Ω ; 1 M Ω seemed best. The source (cathode) and drain (plate) resistors were likewise varied and the best values are shown. You're welcome to try your hand at improving it.

The etched circuit board shown in Figs. 2 and 3 may be used for constructing the converter. The coil forms I used were Cambion SPC-1, 3/16" diameter and 3" high.

It only took two evenings to lay out the circuit and etch the board, and assemble the converter. When I tried it out, I was pleasantly surprised at its excellent performance. It outperforms my other transistor converter and can't seem to be overloaded.

... W5JSN

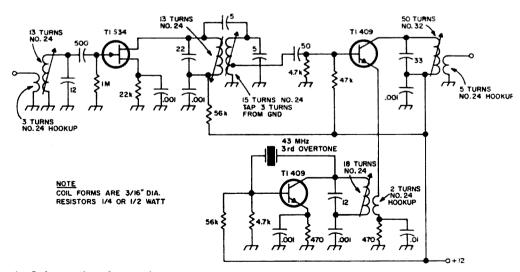

Fig. 1. Schematic of the simple six meter converter with an FET rf amplifier. A suggested etched circuit board is shown in Fig. 2.

Fig. 2. Copper foil side of the etched circuit board for the six meter converter. The board is available for \$1 from the Harris Co., 56 E. Main Street, Torrington, Conn.

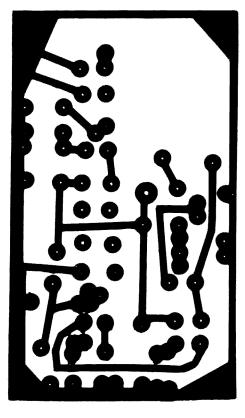

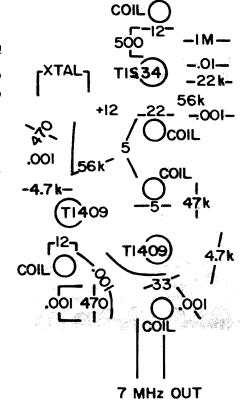

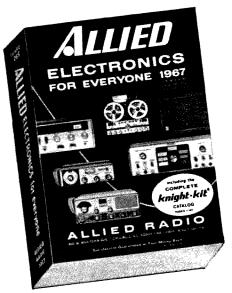

Fig. 3. Component side of the etched circuit board. The coil forms are standard etched circuit types.

Autostart Teletype Encoder and Decoder

Like to get in on the RTTY fun? Here are a pair of excellent transistor projects that will get you on quickly without fuss and trouble. Circuit board layouts are included and the boards are available if you prefer to buy them. Good for AFSK VHF or RFSK HF.

The VHF amateur who is interested in establishing dependable communications between his friends in his own area should be interested in a method of improving that dependability. It is called autostart Teletype and is used in amateur activities that center around one particular channel which is used by many people as a calling frequency. Although employed to a limited extent on the low bands, autostart Teletype proves to be most useful between club or net members using the VHF bands for local communications.

Autostart means "automatic starting" and this is exactly what the name is meant to imply. As an example, suppose you have a receiver monitoring your favorite channel. While you are out one of your friends calls you on the radio to give you a message. When you don't answer he turns on his teletype tone. Your Teletype machine starts up, prints his message and shuts itself off again, all automatically. When you come home the message is there, waiting to be read. The possibilities of this system are virtually limitless.

Teletype decoder

The Teletype decoder (converter) to be presented here was designed for VHF activity using AFSK* (audio-frequency shift keying). It was revised a few times to make it simpler, cheaper and more compatible with existing

equipment. The result is a solid-state unit which will run for years in continuous use without maintenance. It is simple to build and will cost very little in the way of parts. The printed circuit board for the unit is larger than necessary so as to provide plenty of space for odd-sized parts. It may be copied directly or you may wish to design your own.

The decoder works in the following manner: The input audio is limited, amplified and then split to separate channel filters. Q2 is the 2125-hertz (mark) filter and Q3 is the 2975-hertz (space) filter. The audio is then rectified and filtered to de which is fed to a divider network consisting of two 56-k Ω resistors. With respect to ground, the junction of these two resistors swings positive and negative on mark and space tones.

Transistors Q4, Q5 and Q6 form the dc coupled amplifier which drives the printer magnet and turns the current on and off. The diode D7 helps shut off Q6 completely and also acts as a fuse to protect the transistor junction against execessive currents.

Transistors Q7, Q8 and Q9 also act as DC switches. The zener diode D8 prevents triggering on random noise and voice. The resistor-capacitor network between Q8 and Q9 forms the on/off time constants for the autostart section. There is a delay of about one second from the time the mark tone is applied to the input until the relay pulls in and about three seconds delay for the relay to drop out when the tone is released. These time constants prevent the machine from coming on during noise and

^oIt may also be used for HF frequency shift RTTY by leaving out or ignoring the connections to the autostart circuitry (Q7, Q8, Q9 and the autostart relay).

voice reception and also prevent the machine from shutting off during high space content transmissions.

The relay employed at the output of the autostart section is a small, sensitive, 24-30 volt sealed type which only requires a few milliamperes of current to pull in. If you can't find this type, a higher current relay can be used provided that Q9 is chosen so as to handle the power. The contacts of any relay you use must be capable of handling 110 volts ac at about 2 amps. This means that it will be necessary to drive a large 24 volt relay from the small one if it is used.

Many different types of transistors will work in this unit and I would urge you to try the ones you have before you go out and buy. Except for Q6 and Q9 the parameters are not critical. The type shown in the diagram are the type I used. General purpose, silicon audio types with medium betas will serve just fine. For Q6 a power transistor in a TO-3 case was used. It will require no heat sink. Select one with a low leakage current. For Q9 be sure it will handle the relay current you plan on using. The one specified in the schematic is good for about 50 milliamperes.

Once the components are mounted the decoder can be tested in the following manner. Check all diodes to be sure they are in correctly. Remove Q4 and the zener diode D8 from the circuit and apply power. Place an audio tone of either mark or space on the input and check for audio with a scope or high impedance crystal earphone at test point 1. At point 2 the level should be higher. At point 3 the mark tone should be stronger than the space tone and at point 4 the space tone should be stronger than the mark tone.

Connect a VTVM to test point 5 and switch back and forth between mark and space tone. On mark the voltage should go about 5 volts negative and on space it should go about 5 volts positive (Q4 and D8 must be disconnected for these readings). The swing can be greater, but less than plus or minus 5 volts indicates possible malfunction. If the mark and space voltage at point 5 differ by more than .3 volts it would be advantageous to adjust R1 and R2 so the gain thru both channels is equal. This point is a discriminator type output which, like an FM receiver, will tend to cancel noise and random audio interference.

If all checks out, insert Q4 in the circuit and adjust R12 until the magnet current is 60 milliamperes° with the mark tone on. The value

^oThis will allow either series or parallel configuration on the magnets by simply adding a resistor in series with the magnet for 20 milliampere operation.

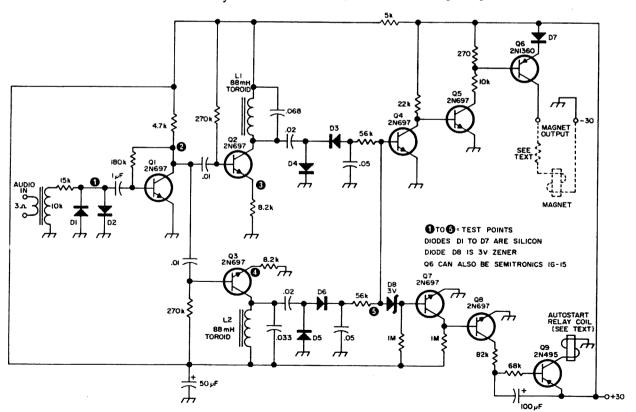

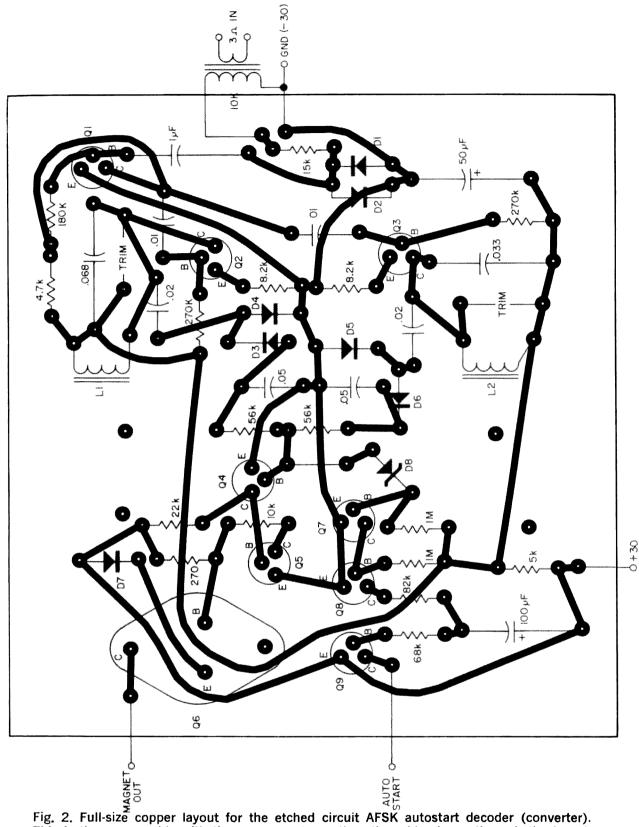

Fig. 1. Schematic of W6AYZ's decoder (converter) for VHF AFSK autostart RTTY. It can also be used for HF RTTY, but the autostart circuitry might prove unreliable for this use, so it's best to ignore it.

This is the copper side with the components on the other side shown through the board.

shown is a nominal value. Switch to space tone and the magnet should no longer hold in, even when manually depressed.

Finally insert the zener diode D8 in the circuit and apply the mark tone to the input. After approximately one second delay the autostart relay should pull in. Release the mark tone and measure the time it takes for the relay to drop out. This should be about three seconds. These times can be longer but will cause trouble if they are shorter.

This completes the checkout of the Teletype decoder and it should be ready to place in service. The range of the machine will be slightly narrower than on local loop but if the decoder is adjusted properly the loss should not exceed 10 points.

Teletype encoder

The Teletype encoder is really an audio oscillator with a transistor switch and is used for the transmission of Teletype signals by modulating the carrier. Two tones are used, the mark tone (2125 hertz) and the space tone (2975 hertz).

The encoder can be built on the printed circuit card or any other way you may choose. Only frequency determining components are critical in this circuit and many types of transistors will work equally well here. The audio output is enough to drive any transmitter including carbon mike types. An external potentiometer should be used to control the level of the generator.

The only difficulty you may encounter is getting Q4 to switch from space to mark. First try a few different types of transistors and if that fails juggle the values of R10 and R12 around. The beta of the transistor is most likely the gremlin in the problem. If it is too low

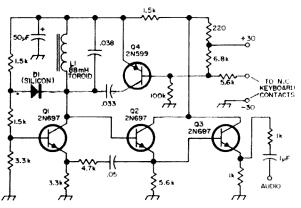

Fig. 3. Schematic of the AFSK RTTY encoder (generator). This circuit generates 2125 and 2975-Hz tones used to modulate AM transmitters for VHF RTTY.

the mark tone will not come on and if it is too high the space tone may not come on.

There are many things you can do with your new system and you will spend many happy months discovering new uses. Nets, field days or just plain fun will convince you that VHF Teletype is most useful and here to stay.

Transistor Tester for VOM's

Check current gain, shorts and opens with this simple adapter.

Like most of you, I have always desired and half-way needed a reasonably good transistor checker. The problem has been that the ones available in the \$7.00 to \$10.00 price bracket are practically useless, and the actual need never seemed to warrant the investment for a decent checker. The checker described here provides a reasonably good solution to this dilemma.

If you have any kind of a junk box, this transistor checker adapter for your VOM or VTVM will cost considerably less than the ready-made cheapies, and it will give more test data. Getting down to details, you can check current gain, determine which junction is open or shorted, and check for leakage.

The circuit

The adapter tester utilizes a standard common-emitter circuit as shown in Fig. 1. Hence, devices are being checked under typical working conditions. Here is how it works. With R4 set at zero resistance, the base voltage will be equal to the voltage $V_{\rm B}$ which is 6 volts (less a tiny drop across R3). Then, depending upon if the transistor is germanium or silicon, there will be from 0.3 to 0.7-volt drop across the base-emitter junction. Thus, with a good transistor in the circuit the remainder of the voltage will be dropped across R5 giving a meter reading of about 5.5 volts.

Checking transistor defects

With S2 in the test position and R4 set at

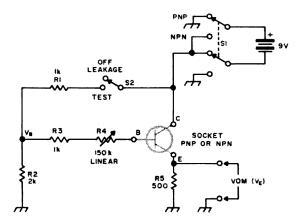

Fig. 1. Transistor tester adapter for use with a VOM.

zero, faults are checked as follows:

- 1. A collector-emitter short will give a meter reading equal to the full battery voltage (9 volts).
- A collector-base short will also yield a full supply voltage reading.
- 3. A base-emitter short will produce a 2-volt reading on the meter. There is no transistor action, hence, R₃ and R5 function as a voltage divider.
- An open collector will also give a 2volt reading.
- 5. An open base or open emitter—no reading.

All of these meter readings are fairly widely spaced for easy recognition of a particular transistor defect.

Accurate beta measurements

By now, you are probably wondering why R4, and 150 $k\Omega$ linear potentiometer, is in the tester. Well, this is used to make rather accurate beta measurements.

By performing a circuit analysis, it can be shown that the voltage $V_{\rm E}$ across R5 is a function of $V_{\rm B}$, R3, R4, R5 and the gain of the transistor. We won't bore you with the math details, just take our word for it. Ac-

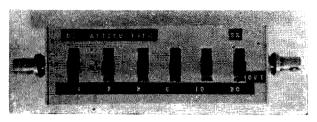

tually, the equation boils down to $\beta=\frac{}{2R5}$ if $V_E=2,$ and, since we have made R5=500 ohms, transistor current gain is equal to R4 in kilohms. Get the idea, all that is necessary to get accurate gain measurements is to calibrate R4 in steps of say $5~k\Omega.$ Then, to measure current gain, simply adjust R4 so that the meter reads 2 volts, and read gain from the calibrated pot. For example, a $50~k\Omega$ reading on the pot (meter set at 2 volts) is equivalent to a current gain of 50.

To check leakage, open S2. A low leakage device will give a very low or zero meter reading. Also, a pair of headphones connected in place of the VOM will give a fairly good indication of transistor noise.

Depending upon the type of meter you own, this adapter checker could be built in a small case outfitted with appropriate plugs spaced to match the jacks on the meter.

Amateur low-power attenuator made from inexpensive slide switches, 5% resistors and fiber glass, copper-clad board.

Low Power Attenuators for the Amateur Bands

Simplified construction, excellent performance and low cost make these attenuators attractive to the ham. They're good to over 450 MHz.

In the evaluation of rf amplifiers, filters and many other devices, a variable attenuator is indispensable. This article describes attenuators built and tested by the authors. These attenuators are flat from dc to over 50 MHz and usable to over 450 MHz. They use low cost parts, are very simple to build, and are more accurate than ordinarily required in amateur applications.

The basic attenuator section is the symmetrical pi shown in Fig. 1. Resistance values are given by the relations:

$$R_1 = R_s (\sqrt{K} + 1)/(\sqrt{K} - 1)$$

 $R_2 = R_s (K - 1)/(2\sqrt{K})$

where R_s is the characteristic impedance of the pad (equal to the source and load impedance) and K is the attenuation factor, P_{in}/P_{out} .

Resistor values for the most commonly used impedance (50 ohms) are shown in Table 1.

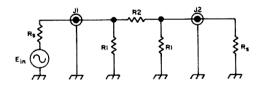

Fig. 1. Basic pi-network attenuator section.

Nominal atten- uation in dB	R: in ohms	R ₂ in ohms	Calculated atten- uation in dB	Measured atten- uation in dB
1	910	6.2	1.1	1.1- 1.2
2	430	12	2.1	2.1- 2.3
3	300	18	3.0	3.2
6	150	39	6.2	6.3- 6.6
10	91	68	10.2	9.6-10.1
20	62	240	19.6	19.5-19.7

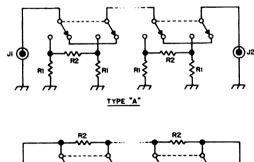

Annenuation measured at 50 MHz and lower.

Table I. Resistor values for $50-\Omega$ attenuators.

Notice that the use of standard value 5% half watt composition resistors allows accuracy within 1 dB of the calculated value of attenuation and within 1 dB of the desired nominal value.

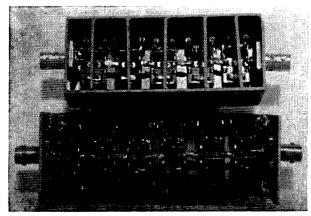

The attenuators are built in small channel boxes made of copper-clad etched circuit board material. Aluminum channel boxes commercially available would probably work equally well. Small, inexpensive DPDT slide switches (H. H. Smith No. 518 or equivalent) are soldered directly to the copper board and the resistors are soldered to the switch terminals (which have been cut short) with the shortest leads possible.

Two wiring variations have been tried, one

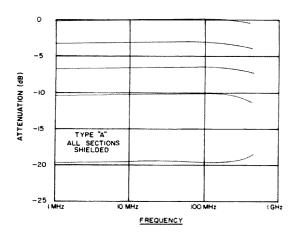

JI RI RI RI RI TYPE "B"

Fig. 2. Two types of attenuator construction. Type A has lower insertion loss than type B at high frequencies, so A is recommended. Resistors R1 and R2 are 5% composition, ½ watt. The switches are H. H. Smith 518 or equivalent. The connectors can be of any type to suit.

Details of attenuator construction. The top style, with complete shielding, is recommended.

with the series resistors (R2) mounted between the switch wiper contacts (type B), and one with all resistors connected to the attenuator in terminals (type A). See Fig. 2 and the photo of the interior of the attenuator. It was found that the latter arrangement, type A, provided less insertion loss than the former at high frequencies, so this type of construction is recommended. Also note that dividing shields are desirable between input and output elements of a single section. These shields prevent capacitive feedthrough at the high frequencies, and are desirable on the high attenuation sections (anything over 10 dB) even at low frequencies. On the low attenuation sections, very little difference is evident below VHF. See Fig. 3 for the attenuation of the attenuators up to over 450 MHz. Building attenuators with greater than 20 dB at-

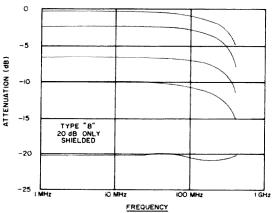

Fig. 3. Insertion loss versus frequency for the two types of attenuator construction: all sections shielded (A) and only the 20 db section shielded (B).

tenuation per section by this method is not recommended for high frequency use.

An FET S-Meter

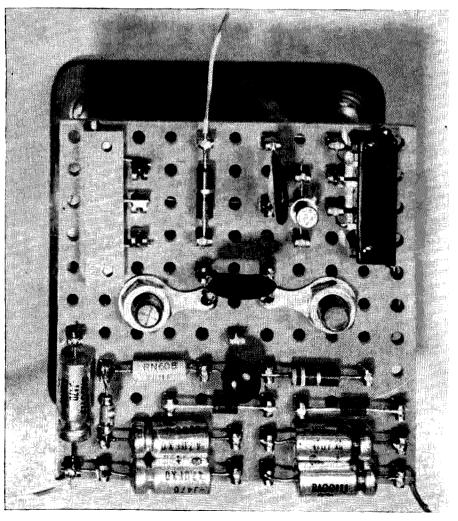

Here's another useful application of field effect transistors.

For the ham "who has everything" the addition of an "S"-meter is no problem; the "S" meter comes with the "S" line. However, for those of us who build our own or modify surplus receivers, adding a signal strength meter is not always an easy task.

Most communication receiver manufacturers design their S-meter into the receiver as an *if* amplifier plate-current meter. This allows the use of a 0-1, 0-2, or 0-5 mA meter movement, which is about the cheapest of the movements. In this type of "S"-meter, the *if* plate current decreases as the (negative) AGC voltage increases. In other words, *the*

meter reads backwards! For a manufacturer making a large production run, "backwards" meters are only slightly more expensive than standard meters; so this simple method has economic advantages. But for the homebrewer of receivers, a standard meter must be used upside-down, and a new scale put on it.

Another approach to an "S" meter is to use the "VTVM," circuit, or differential triode amplifier. Such a circuit can be made to drive the meter in either direction, depending on which meter terminal is connected to which triode. In Fig. 1, the meter is connected as it would be for use with the negative AGC line

FET S-meter circuit built on a piece of Vector board that is fastened to the back of the meter used. The linear, 15 turn pots in the upper corners can be Bourns E-Z Trim types costing only \$1.85 apiece. of a receiver. A variation of this circuit replaces V2 with a resistive voltage divider, as in Fig. 2. In either the circuit of Fig. 1, or that of Fig. 2, an extra tube must be added to the receiver.

One way to implement the VTVM circuit is to remove a dual diode-triode (second detector, first audio amplifier, like a 6SQ7, 6AT6, or 6AV6) and replace it with a compactron and a couple of semiconductor diodes. The newer GE 6C10 and 6D10 are triple-triodes, that could serve as both audio amplifier and VTVM differential. Such a modification requires a socket change, of course.

A simpler solution to the "S"-meter problem has the negative AGC voltage drive a "P-Channel" field effect transistor (FET). The "P-Channel" FET compares to a vacuum tube except that it is a tube's complement. That is, drain (plate) voltage is negative with respect to the source (cathode), and a negative voltage applied to the gate (grid) increases drainto-source current flow. If we use this "P-Channel" FET as a meter driver, negative AGC voltage applied to the gate will increase the meter reading, as we desire.

The FET "S"-meter is shown in Fig. 3. It can be operated from the AGC line of nearly any tube-type communications receiver. Notice that the circuit is complete with a -11 volt regulated supply that takes its power from the 6.3 volt heater circuit. Therefore, only three connections are necessary; heater, AGC line, and ground. The photo shows the circuit as it was constructed on vector board, to mount on the back of a 3", 0-1 mA meter.

In Fig. 4 are shown the characteristic curves for the 2N2606 through 2N2609 family of P-Channel FET's. The family of curves shown really represent only the 2N2608, but by applying the scale-factors in the accompanying table, the rest of the family can be calculated. The near-equivalent industrial versions of these FET's have been added to the table, because these less expensive types are the ones hams will be most likely to use.

Since these four types of Siliconix FET's differ in both price and current ratings, we have a tradeoff situation. The U148 will drive a 1 mA movement, and it costs \$4.10. The U147 will drive a 500 µA movement and it costs \$2.95. The U146 is more expensive than the U147, and has less transconductance, so represents a poor choice for this application. The U149 will drive a 3 mA meter, but the price is \$6.50. The prices of the four FET's and the prices of the various meters must be considered in deciding which to use. It appears that the U147 and a 500 µA meter would represent the best combination, if one is buying all new parts.

The circuit of Fig. 3 was constructed and set up to give a full scale reading of 1 mA when -7.5 V dc was applied to its input. The response is shown in Fig. 5A. With this sensitivity setting, the circuit was connected to an ancient Hallicrafters S-series communication receiver, and the sensitivity curve of Fig. 5B taken.

The curve of Fig. 5B, while nonlinear in terms of mA per dB, is still quite useful. If one really wants a scale that reads "S" units, a paper scale can be added to the meter movement.

James Ashe W2DXH R.F.D. 1 Freeville, N.Y.

Unwanted Feedback

It's happened to all of us! It happened to me. I built a high-gain audio amplifier. I proudly believed I had thought of everything. Let's see, now. Output and input circuits well isolated. In two separate chassis, in fact. A 140 µF capacitor across the power supply output. Decoupling of all the circuits and double decoupling, with large electrolytics, of the input circuits. Feedback? Hah.

Report: Feedback. Motorboating at two seconds per cycle (½ Hz). Also oscillations at 120,000 cycles per second (120 kHz).

Solution: Imaginative application of the following.

Feedback theory

The key to the entire problem of unwanted feedback lies in Fig. 1. This illustration shows in block diagram form a 'feedback loop'. The two boxes and the circle add up to a circuit having the special property that, in some direct or devious way, part of the output signal finds its way back to the input terminals of an amplifying element. This key concept is applied to any particular problem by looking for the parts of the actual circuit which correspond to the different parts of the diagram.

More complex feedback loops may be made up by elaborating this diagram. But accidental loops are increasingly unlikely in proportion

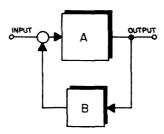

Fig. 1. The basic feedback loop, an essential tool for modern circuit design but a great troublemaker when it occurs accidentally.

to their complexity. Such circuits are used in design work, however, for better circuit performance than single loop designs can deliver. A quite elaborate system is shown on page 42 of the February 1965 issue of Popular Electronics. And Jim Kyle, in his article on selective filters in the July 1965 issue of Electronics World, describes a filter circuit having two feedback loops around a single transistor.

The summing point, represented in Fig. 1 by a circle, is a good place to start explaining this circuit. It is the point where the input signal and the unwanted return signal meet to continue along the same route through the amplifier A, which may be anything from a single transistor to a complete chassis. In feedback problems, the amplifier A probably involves only two or three tubes or transistors. The amplified signal leaving A proceeds mostly to the output, but a little bit of it finds its way back through the return network B to the summing point. The properties of B are very important, since this usually is the part of the loop most easily attacked to get rid of the unwanted feedback.

When the return signal passes through A it is delayed. It comes out a little after it goes in. The signal is further delayed in B, and the total amount of delay has a powerful effect upon the results of the unwanted feedback. For engineering design work, this delay and its detailed effects receive careful attention. It's not so important here, where the major purpose is merely to find and remove the offending, parasitic circuit.

However, one question may be asked. Is it possible that an accidental feedback loop might cause no trouble? Except for unwanted loops whose effects are so weak they cannot be detected or at least do not disturb normal operation of the circuit, the answer is no. The reason is that the properties of accidental loops will generally show a strong frequency dependent factor. If the feedback is strong enough to be noticed, there will almost certainly be one or several frequencies at which everything will add up the worst way. The only safe course is to eliminate the feedback.

For engineering purposes there are several basic types of feedback. These can be sorted out into two types: feedback which leads to oscillations, or positive feedback; and feedback which reduces circuit performance, or negative feedback. There is no reason why accidents of nature or construction should emphasize one over the other. The two kinds are equally likely!

Positive feedback acts to increase circuit gain. In extreme cases it leads to uncontrollable oscillations. Motorboating is a form of

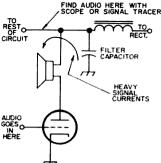

Fig. 2. Showing the route of output stage signal current through the power supply filter capacitor, which feeds audio back to the rest of the circuit.

oscillation, commonly involving a loop through several stages of amplification, and back through a supply line to the input stage. Other effects are increased noise, snapping, clicking and ringing, gain variations greater than control adjustment should produce, and disturbance of tube and transistor operating points leading to severe distortion, or in extreme cases, apparent failure of the circuit to do anything at all.

Negative feedback is less obvious, and may seem to result in improved operation of the circuit. The trouble shows up when estimated circuit gain is much greater than measured circuit gain, when filters show less selectivity than they should be capable of, when gain controls appear ineffective, and when the general performance of the circuit seems to vary from time to time.

Feedback routes

When a feedback problem has been identified, the next question is: which parts of the circuit are involved? In general the exact route will not be obvious, or it would have been eliminated while constructing the circuit. And if a particular lead or component is definitely found to be carrying some unintended signal, is that signal cause, effect, or irrelevant? For example, if the first two stages of an amplifier are oscillating, their signal will be found right down through the rest of the system.

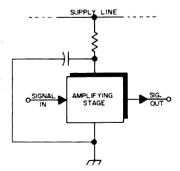

Fig. 3. A single gain or oscillator stage supplied through an isolating resistor and grounded at a single return loop for nearly-perfect isolation. Very good for BFO's.

A FIRST CLASS FCC LICENSE

...or your money back!

YOUR key to future success in electronics is a First-Class FCC License. It will permit you to operate and maintain transmitting equipment used in aviation, broadcasting, marine, microwave, mobile communications, or Citizens-Band. Cleveland Institute home study is the ideal way to get your FCC License. Here's why:

Our electronics course will quickly prepare you for a First-Class FCC License. Should you fail to pass the FCC examination after completing your course, you will get a full refund of all tuition payments. You get an FCC License . . . or your money back!

And only CIE offers you new, up-to-the-minute lessons in all these subjects: Logical Troubleshooting, Microminiaturization, Single Sideband Technique, Pulse Theory and Application, Boolean Algebra, and many more.

You owe it to yourself, your family, your future to get the complete details on our "proven effective" Cleveland Institute home study. Just send the coupon below for FREE book or write to Cleveland Institute of Electronics, 1776 E. 17th St., Dept. ST-9, Cleveland, Ohio 44114.

ENROLL UNDER NEW G.I. BILL

All CIE courses are available under the new G.1. Bill. If you served on active duty since January 31, 1955, OR are in service now, check box in coupon for G.1. Bill information.

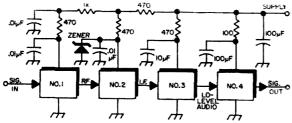

Fig. 4. A decoupling system that might be used in a receiver. Stages 1 and 2 are super-decoupled. The zener improves voltage regulation, spoiled by the decoupling resistors. Zeners are sometimes noisy and should be bypassed in audio and oscillator circuits.

Supply wiring, which goes all over the chassis, is the most likely candidate for feedback routes. In general, this supply wiring is inadequately bypassed. The supply filter will often have the smallest possible capacitors, as estimated from a hum viewpoint. This may be a false economy. For example, motorboating at around twenty hertz is not unusual. What are the reactances of various sizes of filter capacitors at this frequency? A 20 µF capacitor will have a reactance of 400 ohms. A relatively small audio output stage can produce 10 volts across that! And at high rf frequencies supply lead reactance becomes an important factor. Valley and Wallman cite about 8 ohms per inch of wire at 60 MHz. Prorate that to 420!

Common capacitance between two points is another cause of unwanted feedback. Builders of compact equipment probably see a lot of this. Even at audio frequencies two inches or so of clear space between two tubes may not be sufficient. This kind of coupling is avoided by building the system in a straight line, and by some careful positioning of components.

Inductive coupling is a third possibility. All components, from wires to transformers, are surrounded by magnetic fields produced by the currents flowing through them. The field is generally weak and other components are little affected. Sometimes there is trouble. The two cases in which magnetic coupling is most likely are those in which ordinary chokes or solenoidal coils are being used in selective audio amplifiers, and rf amplifiers with tuned input and output coils located on the same side of the chassis.

Waveguide coupling, saved till last, is perhaps the most surprising kind of unwanted feedback. A closed chassis . . . very good practice! acts as a waveguide even though the wavelength may be much greater than its dimensions. It's a very poor waveguide, but it's good enough. Valley and Wallman cite 30 dB

per length equal to width. If the chassis is 5 inches wide, a popular size, that's 30 dB per five inches, far less than the circuit gain now possible in the same distance.

Removing feedback

Very few feedback problems require more than one or two small changes for complete elimination. The problem is to find out what change is required. By putting in additional capacitors, new decoupling, revised grounds, different tubes and transistors, cut and try methods may more or less solve the problem. But there's a better way to do it. Identify the loop and tackle it at its weakest point.

No rules can be given for this. What has to be done depends on the situation. One problem will be obvious, another may be quickly seen through by a seasoned veteran. The third may require the complete treatment by an expert. In general, the method is to disable everything that doesn't seem to affect the feedback, search around in what's left, and try to find out which part of the circuit corresponds to each section of Fig. 1. Here are some hints. Microvolt sensitive VHF converters oscillate at volt, not microvolt, levels. The oscillations are easily picked up with probe or absorption meter. If a supply line is suspected, look at it with a scope. Metal plates will shield electrical and magnetic fields at rf but electrical fields only at audio. A tuning stick, iron slug at one end and brass at the other, can be poked into suspected rf circuits to identify parts in the loop, when a screwdriver or your hand will detune everything. If you can't identify the feedback loop, suspect a wiring error that mimics regeneration. Set an alarm clock; if you haven't licked the problem in two hours, put it away and come back next day.

Summary

A newly completed circuit can be a bundle of joy or occasionally a wellspring of terrible frustration. Do not fear the worst! A careful application of your powers of analysis aided by some theoretical background is the most effective approach to any problems that may arise. Unwanted feedback has a cause, a circuit that embodies that cause, and unless you're terribly unlucky it has a simple solution. Read up, and then go at it!

Equipment Protection

Eliminate the devilment of Poof—the Magic Dragon that destroys electronic equipment in seconds.

Something goes wrong in the circuit. The tube plate glows pink, then rapidly red and an orange-white. A bright bluish flicker as the grid shorts to the plate and melts, then all is over. And although your hand was on the plate switch all the time, you never had time to throw it.

Has this ever happened to you? If not, you're an unusual homebrewing ham—or else you don't need to be reading this article. But the odds are it has, at least once. Maybe it was an expensive power tube that went, maybe a power transformer—but few of us have escaped what the reliability engineers call "catastrophic failure" of a component at least once.

The reasons for protective circuitry are obvious; the one most often thought of is to protect the shack from fire caused by overload wiring. Others, frequently of more practical importance, include protection of individual components (such as tubes) from overloads, and the protection of complete items of equipment (such as power supplies) from the same source of possible harm.

To achieve all these aims of protective circuitry, the conventional power-supply-primary fuse (the one most often included in the rare cases that any fuse appears at all) is not enough. After all, a fuse which will permit enough power to pass to light several dozen watts of heaters can hardly protect a screen circuit from a 60 mA destructive overcurrent!

On the other hand, individual fusing of each stage could rapidly turn into a supercomplex project when the full complement of gear in a well-equipped station is considered. Obviously, some form of compromise is necessary.

The nature of this compromise is such that you'll have to determine for yourself just where to make it. To give you the information on which to base your decision, let's look at the places that fuses can provide protection.

Fig. 1 shows a typical HV power supply, while Fig. 2 is a partial schematic of a transmitter's rf section. The possible places for fuses are indicated in each case.

In Fig. 1, note that each transformer is individually fused. While this admittedly requires a few more fuseholders and fuses, it also allows you to install a fuse which will pass the required amount of current to each transformer, yet will blow on slight overload.

The secondary fuse shown from center-tap to ground in Fig. 1 protects the transformer itself against overload; if its value is properly chosen it can also protect the chokes and (to a lesser extent) the rectifier tubes.

In Fig. 2, the fuse in the driver plate circuit serves a dual purpose. It protects the tube against extreme overloads, while protecting the power supply and divider circuitry in case the tube shorts out.

In the final, two fuses are recommended as shown. The one in the screen circuit should be selected to blow instantly when maximum screen input (determined from tube charts) is exceeded. When you realize that high-power tetrode can destroy itself within less than a second with excessive screen current, you understand the necessity for a fast-acting fuse here. The plate-circuit fuse, on the other

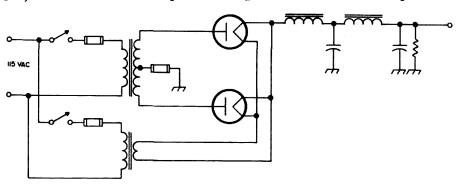

Fig. 1. Fused power supply.

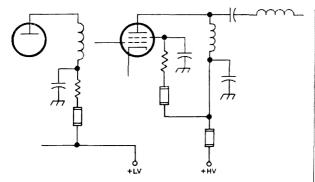

Fig. 2. Fusing the transmitter.

hand, offers only conventional overload action. If protection of the supply is the major item of importance, all the low-power stages can be grouped through a single fuse. If, on the other hand, protection of the tubes is the important thing, then a separate fuse in each circuit is the way to do it. Usually, you'll want to protect the final tube, but in the driver stages it may be more worthwhile to simply protect the supply and let the tubes take the risk.

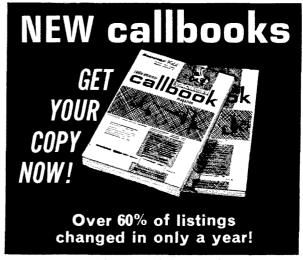

In the case of receivers and test equipment, the power supply fusing shown in Fig. 1 is usually adequate. This is especially true if the secondary fuse is chosen to just pass the normal maximum operating current so that it will blow at overload.

At this point a look at some of the various types of fuses is in order. The "ordinary" fuse actually comes in three varieties—and use of the wrong type can easily rob you of the protection you think you have.

Most widely known, of course, is the garden-variety fuse. This type normally carries its rated current without damage, but blows within 10 seconds when double the rated current flows. More severe overloads blow it faster, but the time required to interrupt the circuit seldom falls below a couple of seconds.

When protecting equipment which cannot stand such overloads for even this short time, the "fast-acting" fuse is the one to use. This type has a spring in it to speed the action (in the smaller sizes, the spring may consist simply of the fusible wire itself) and may be used to protect the screen circuits of such power tubes as the 4X250 and the 4-1000.

Circuits containing heavy inductive loads, such as motors which must start under load, frequently draw 10 or more times their rated current at the instant they're switched on. If either a normal or a fast-acting fuse is used to protect such a circuit, it would blow every time the switch were thrown. The "slow-blow" fuse was developed for this type of circuit; it withstands heavy overload for several

seconds and blows only on sustained overload. Such fuses have no place in radio circuits; they're mentioned here only to warn you against them. Many a lost power tube can be traced to the inadvertent use of slow-blow fuses in screen circuits!

So far, we've talked only about fuses. This suicidal little component is one of the simplest and surest ways of protecting electrical circuits—but it's not the only way.

Another protective device which does the same job but doesn't destroy itself in the process is the circuit breaker. Within the past few years, small circuit breakers have been developed for television sets which trip at 2 or 3 amps and can be purchased for only a dollar or two at most suppliers. These are ideal for primary-circuit protection in power supplies wherever their ratings apply.

A similar device is the overload relay; this can be a special unit (with correspondingly high price) or, in many cases, can be a conventional relay wired to interrupt the critical circuit whenever current drain exceeds a specified limit and to then hold the circuit broken until it is reset. Since such a device acts faster than most fuses, it is correspondingly better for screen-circuit protection. Fig. 3 shows one way of using an inexpensive relay in such an application. The pot across the coil acts as a shunt and is used to set the current at which the relay will trip. The normally-closed pushbutton is the reset switch. The load resistor (RL) is chosen to draw slightly more current than the tripping value, to insure that the relay remains closed after it trips.

Often, the circuit to be protected with a fuse, breaker, or overload relay happens to be one in which you would also like an indication of relative current flow. If the accuracy of a meter is not required, and if the current flow is normally between about 30 and 250 mA, you can kill two birds with a single pellet by using

an ordinary pilot-lamp bulb as a combined "meter" and fuse.

These bulbs are normally rated for currents of 60, 150, and 250 mA. At half rated current, they emit a readily visible dull red glow. At rated current, of course, they have their normal appearance. At approximately 25 percent over rated current, their light becomes a searing blue-white, and if the current goes much higher they burn out as rapidly as an ordinary fuse.

Thus a 60 mA bulb provides a good indicator in the range from 30 to 75 mA, with protection at about 100 mA. A 150 mA bulb covers the range from 75 to about 185 mA, blowing somewhere around 250 to 300 mA. And a 250 mA bulb covers the range 125 to 310 mA, letting go about 450 mA or so.

It's best to use the highest-rated bulb that will give you both the indication you seek and some measure of protection, because bulb life is related directly to current flow. At 5 percent under rated current, bulb life doubles—but at only 5 percent above rating, the life of the bulb is cut in half! This means that, at 200 mA in the circuit, a 250 mA bulb would outlast a 150 mA bulb by dozens of times over. However, it would require half again as much drain to blow.

In the old days, before World War II and the resulting inexpensive surplus meters, this bulb-fuse trick was widely used in even sophisticated gear. Now, it's hardly ever seen. However, it's still good and is especially handy in portable and mobile apparatus where it helps hold down size and weight.

Since the bulbs do have limited life, it's recommended that you use sockets for them. The socket can easily be mounted on a quarter-inch standoff insulator, providing a handy tie point for the high-voltage line.

Incidentally, you don't need to worry about the voltage rating on a bulb used in this application; it will take care of itself when rated current flows. As a case in point, the author has successfully used a single 250 mA bulb in the high-voltage line to a pair of 6DQ6's operating at 500 volts, 200 mA. Once the parasitics were removed from the rig (they turned the bulbs brillant blue instantly), bulb life proved to be almost indefinite. And as an aside, the variation in brightness during tuneup was far easier to see than the gyrations of a plate meter!

Which brings us to the end of this roundup of equipment protection tricks and techniques. Remember, next time you build something—put in what the designers left out! It's not only safer that way, it's cheaper, too!

An Etched Circuit UHF Dipmeter

These dippers cover 130-480 MHz, yet aren't critical, hard to build or expensive.

In the December 1965 issue of 73, Paul Franson WA1CCH, described a simple UHF dip meter. It worked well, but was difficult to package satisfactorily. I did some playing around with the circuit and found that it wasn't hard to modify it slightly, put it on an etched circuit board, and make a nice looking, convenient set of VHF-UHF dippers. The etched circuit board construction makes the dippers easy to duplicate, and the flat, U-shaped inductors are convenient to fit into tight places that conventional coils can't reach.

For a discussion of the circuit, see WA1CCH's article. There was a minor error in the article. In **Fig. 1**, the oscillator should be described as a grounded base rather than as grounded emitter oscillator.

I made three models of the dipper. They cover 130-175 MHz, 175-250 MHz, and 250-480 MHz. The first two models use the same size inductor, with the 130-175 MHz model using a larger capacitor for tuning with a ce-

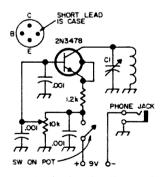

Fig. 1. The etched circuit dipper is very simple. The circuit is almost identical to the one described by WA1CCH in the December 1965 73, but the construction is quite different. C1 is Johnson 160-104 (9 pF) for the two higher frequency dippers, and 160-107 (14 pF) for the 130-180 MHz model. There is a trimmer across C1 in the 130-180 MHz model; see text.

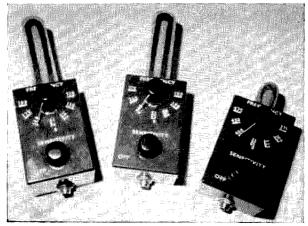

ramic trimmer across it. This trimmer is not shown in the schematic; its value is 7-45 pF and it should be adjusted to cover the proper range.

The 250-480 MHz dipper uses a smaller inductor than the others. It also has a copper jumper (shown in the layout) that the lower frequency dippers don't have.

Each dipper is complete (including the battery) except for the meter. The meters were omitted to save space and money, but can be included if you wish to use a slightly larger case.

Each dipper uses one RCA 2N3478 NPN silicon transistor. These transistors cost only \$1.90 apiece, but it's likely that other transistors that are even cheaper could be used. The 2N3478 has odd basing—the only reference is the short case-shield lead—so don't shorten any leads until you're sure that you can keep track of the connections.

The copper side of the board for the dipper is shown in Fig. 2 with the component side in Fig. 3. You can buy the boards already etched for \$1 apiece from the Harris Co., 56 E. Main

The three dippers shown here cover 130-480 MHz.

St., Torrington, Conn., or make your own. Use glass or Teflon based board. Paper or bakelite board probably wouldn't be satisfactory. Trim the board to the proper shape with a nibbler. The inductor should be coated with coil dope to keep from shorting it when you use it.

To mount the boards, you'll have to cut a thin slot near the edge of the Minibox used as a case. One way to do it is to drill a number of holes of the proper size in a row, then use a file to finish the slot. You'll have to bend that side of the Minibox out to get the board in. It's held in place by an extra set of nuts on the shafts of the potentiometer and the tuning capacitor. Be sure to trim the leads projecting from the copper side of the board so that they won't touch the metal of the case. The battery is held in place with a simple clip made from scrap metal.

The dipper is very easy to use. But before we get to that, let's check it out and calibrate it.

Plug a 2 to 5 mA meter into the meter jack. You can use a more sensitive meter if you shunt it with a resistor that gives the proper scale. Put the resistor across the meter jack terminals in the dipper if you use the meter for other things.

Turn on the dipper by twisting the potentiometer knob clockwise until it clicks. The meter should show very low current. As you turn the pot, the current should suddenly jump to about 1 mA. That means that the transistor is oscillating. If you touch the coil, the meter reading should drop and the dipper may stop oscillating completely. Now tune the capacitor through its range. There should be a little variation in current, but not too much.

Now you're ready to calibrate the dipper. The easiest method is a sensitive wave meter that covers the range, but it's quite easy to do the job with a TV set. A TV set covers 176 to 216 MHz (channels 7-13) for the low calibration. Then the second harmonics of the dipper tuning 235 to 445 MHz can be received on a UHF TV set (470-890 MHz). If you have a two meter receiver, that gives you another maker at 146 MHz. You can put on the panel markings with Ami-Tron or Datak rub-on lettering.

The dipper should be complete now, and ready for use. Bring the dipper near a resonant circuit in the dipper's range and tune the frequency control. You should get a prominent dip in current when both circuits are tuned to the same frequency. The amount of dip depends on the setting of the pot in the dipper, the distance from the tuned circuit, the Q of the circuit, and the type of coupling.

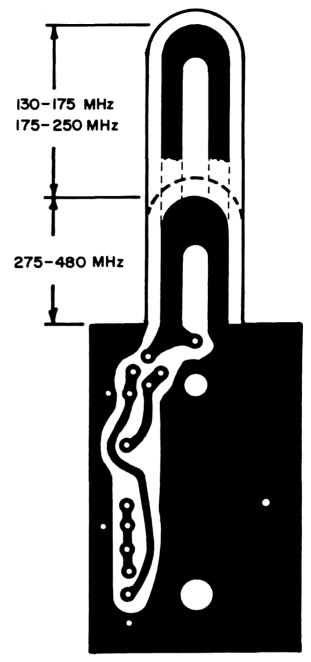

Fig. 2. The copper side of the etched circuit board used in the dipper. This layout is full size. Use board suitable for these frequencies: fiber glass or Teflon. You can buy boards already etched, but not drilled or trimmed to size, for \$1 apiece from the Harris Co., 56 E. Main St., Torrington, Conn.

In many cases it's easiest to leave the dipper stationary and tune the other circuit.

The dipper can also be used for monitoring AM transmitters by plugging a set of headphones in the meter jack and adjusting the tuning and pot. You can also use the dipper for determining the frequency of another oscillator. Simply tune the oscillating dipper with headphones plugged in until you hear a slight

SUB-MINIATURE SOLID STATE TV CAMERA

The VANGUARD 501 is a completely automatic closed circuit television camera capable of transmitting sharp, clear, live pictures to one or more TV sets of your choice via a low-cost antenna cable (RG-59U) up to a distance of 1000 ft. without the need for accessories or modifications on the TV sets. The range can be extended indefinitely by using line amplifiers at repeated intervals or by using radio transmitters where regulations permit.

There are hundreds of practical uses in business, home, school, etc. for any purpose that requires you or anyone chosen to observe anything taking place anywhere the camera is placed. Designed for continuous unattended operation the all-transistor circuitry of the 501 consumes only 7 watts of power.

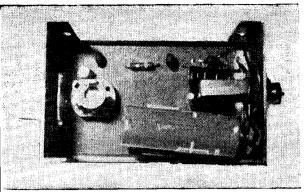

SPECIFICATIONS: Measures 23/4" x 4" x 7" (excluding lens and connectors) • Weighs 31/2 lbs. • Operates on 100-130 volts 50 or 60 cycles, 7 watts • Tested at 10° to 125° F • Advanced circuitry utilizing 35 semi-conductors most of which are silicon • Field effect input circuit for minimum video noise • Resolution guaranteed to exceed standards set by 525 line TV receivers • R.F. output 30,000 microvolts adjustable for channels 2 to 6 • Video output 1.5V p-p composite with standard negative sync (random interlace) • Viewable pictures obtainable with illumination as low as 1 ft. candle • Vidicon controlled light compensation; 150/1. • Adjustable iris on lens enables use in bright sunlight • New long life, subminiature vidicon with spectral response similar to Type 7735A • Electronically regulated power supply and thermally compensated circuits eliminate change in picture quality when line voltage and temperature fluctuate • All parts guaranteed for 1 year (except for open filament on vidicon or breakage) • Fast, low-cost service always available from our factory in Hollis, N.Y.

Pre-set adjustable controls include the following: Video gain, video compensation, pedestal level, target voltage, beam voltage, beam alignment, electrical focus, horizontal frequency, horizontal size, vertical frequency, vertical size, vertical linearity, modulation, and R.F. frequency output.

Send your order direct to our factory at the address below.

VANGUARD LABS

Dept. H 196-23 Jamaica Ave. Hollis, N. Y. 11423

Here's the inside of one of the dippers.

click. You probably won't be able to get a zero beat at these frequencies.

Be careful that you don't use the dipper around an energized transmitter of more than a few watts output or the dipper may be damaged.

These dippers are simple, inexpensive and non-critical to build. After you've build them, you'll wonder how you ever tried to build UHF equipment without a good dipper.

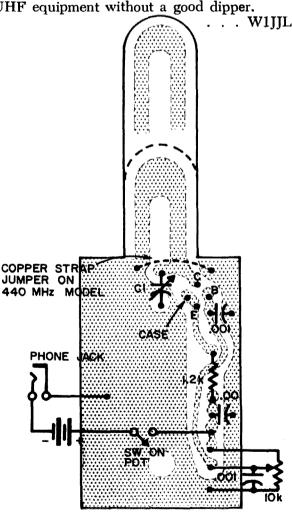

Fig. 3. Component side of the dippers. There is a 7-45 pF ceramic trimmer across C1 in the lowest frequency model. See the text.

Hamming VK9-Style

How'd you like to have to put up an 85 ft. tree trunk for your antenna tower without any skilled help or machinery? Read how they did it on New Guinea.

Truthfully, there is something dramatic about operating a DX-station, but after some of the nasty pile-ups, one soon begins to lose that spine-tingling experience. However, it is still fun to work DX when the conditions are good and some of the signals are of fabulous strength. Then too, while operating a DXstation in Australian Territory, one really begins to respect the capabilities of the Australian gallon, 150 watts. A person can do so well with 150 watts that he might be accused of running a kW, such as I was accused of on a number of occasions. (Incidentally, I had an HT-37, Johnson match-box and rhombic about 5,000 ft. above sea level.) Speaking about power capability, I am reminded of the time when two Florida stations were "chewing the rag" and I heard, "Yeah, we know those fellas in Australia. . . . They say that they run only 150 watts. It's impossible to work DX unless you have a kW."

During the course of the conversation I learned that both operators were running a kW and they lived only a couple of blocks away. I guess they were carried away and forgot the possibility of having an audience and were unaware of being copied all the way down in New Guinea. Anyway, I enjoyed myself and laughed myself sick during the whole conversation. The crowning-point of the whole incident would have taken place if I would have broken in the QSO. I'm sure that there would have been a lot of "hms and haws"

especially if I would have told them,

"The rig here is an HT-37, 144 watts dc."
But I didn't break, however, I had a ball of a time enjoying the QSO of two fellows with the shoe-fever.

I suppose all of the kW-boys have stopped reading. But don't take offense fellas, and be assured that if I could have a kW in New Guinea, that there wouldn't be a happier man. Really, I would be satisfied with a half-agallon, but "it's agin the law." Besides it's more fun working with low power after you get an S9-plus report and you are able to say, "144 watts here."

Another thing which makes life in DXterritory interesting, is the lack of equipment and parts. It's a lot of fun to be able to scrounge around gathering parts, bits and pieces for a master plan. There are no tube checkers, generators kick-out, there is poor regulation on the ac power supply and you blow up the dc power supply on the rig, etc. I remember the time that I blew up one of my silicon rectifiers. . . . I felt like I lost my right arm. But I had a left-handed substitute, an old 5R4G, which I was fortunate enough to have with me. Yes sir, there are no parts stores around here. About the only thing that we have around the corner in New Guinea is maybe a banana tree.

Assembling and erecting antenna systems are no snap either. You don't have ham-

friends to help you when your station is miles from nowhere. As a rule I didn't need an antenna party since labor is cheap in New Guinea. The only problem is that one can't persuade the natives to readily produce said cheap labor.

One of my first antennas was a vertical ground-plane. I built it with scraps of wire, nylon cord from an old parachute, pieces of scrap timber, a few old nails and no soldering iron. It's surprising what one can do while in a pinch. The VGP wasn't too good, though. I was able to get the thing up only 8 feet. The best report that I got was a 5/9, but the usual report was 5/5 to 5/6 and very often the report was 5/3. The good Lord knows how many stations I tried to call and wasn't able to raise with the VGP.

Then I decided to raise the VGP to 50 feet. It took me about three weeks of half-hearted labor from the natives to cut, trim, and drag in a 55 foot tree. After we finally got a hole dug (I had to do most of it myself), I corralled a bunch of school kids from Fatima College. I was superior of the college and the kids had to show-up or else. After raising the pole a few degrees, I was able to mount the VGP. Then in a matter of a few minutes I had my 50 foot VGP. It's surprising what a couple of hundred kids can do if you give them a little direction. But to make a long story short, the VGP was not the antenna for me. Reports were similar to the 8 foot VGP. I guess it was the location in the Waghi Valley. Even though I was located 5,000 feet above sea level the valley mountains bottled-up the rf quite well since the mountains towered over my location another 3,000 to 5,000 feet in some places. With the mountains to the north and the south the only good direction for propagation was toward the east, and a little south of east. Big deal! True, I contacted some of the stations from state-side but signals were poor. The reasons for poor transmission and reception could have been a poor location, poor conditions, or maybe the antenna wasn't up to snuff, and possibly everything together. Your guess is as good as mine in this matter. But one thing I knew for certain was that my heart was not set on developing the VGP. I suppose that I could have narrowed down some of the possible aggravating factors which were causing trouble to the antenna system, but I soon gave up after toying with the probability of moving a mountain or two. But I didn't look at the situation as hopeless. If one can't move a mountain one can still move away from the mountain.

The day of moving to a new location finally came. My stay at Fatima College was com-

pleted and the superior, whose place I was taking, returned to New Guinea. I was then re-appointed to a mission station called Minj. What a place! It was situated on the south wall of the Waghi Valley with a clear shot to the north and northeast. Shortly after I arrived at Minj I hung up an old scrap antenna and fired up the SX-I00. . . . What a shock! Fabulous! State-side was smashing in 20 to 40 dB over S9. Real state-side QRM! That did it. The next day I called for the local tribe leaders and told them that I would like to have four long poles in a week. Surprisingly, the fellows agreed, naturally, for a price. After the leaders left I immediately started digging in my junk trunk. By the time I finished I found enough wire for the big move. I was so happy that I could have jumped up and clicked my heels, but then I began to feel sick with disappointment. Where was the wire for the feed line? Then there was a bout of turning trunks upside down, and clawing through my belongings in hopes to find that wire. Just then, during the height of the confusion, my houseboy arrived on the scene. It was apparent to him that I was looking for something and he asked whether or not he could help. I explained what I was looking for, the roll of wire and all that. The boy got the message for I sensed that the boy felt as if he had done something wrong. Sheepishly, the boy said, "I put that wire in a box in the Tool shed." Man, I could have skinned him alive! But anyway it was a relief to find that wire for the feed-line. Now I could build myself an antenna, the antenna I always dreamed about-the rhombic.

Having located all the wire, parts and rough materials, I was far from being finished, so I discovered later. If anyone tried to cut 6" x ½" spreaders for a fifty foot feed-line, he will know and understand what I mean, especially when all one has is a hack saw and a jack knife. Man, that fiber board was tough!

Finally the poles were brought in and they ranged from 45 feet to 85 feet. They were perfect since I had to build the antenna on the side of a hill and this would help me to shoot the rf over the other mountains in the horizon rather than burn all the grass in the valley. There was still some time left that day after the natives brought in the poles so I had them prepare four big holes and everything was finished by late afternoon. The boys were tired so I thanked them and told them to go home and rest up so that they would be fresh the next morning for the antenna raising.

That night, although I was tired, I was not able to get to sleep. I guess I was a little anxious about the new rhombic, but the big-

gest problem that bothered me was getting up that 85 foot pole in such a way that there would not be a funeral after the antenna raising. Morning came too soon. I was happy with the fact that I would have my first rhombic, but inside I was sincerely hoping

that nobody would get hurt.

It was about 8 o'clock that day when about 15 fellows showed-up. Since I wanted to get the job moving we began on the 45 foot pole. In about 45 minutes or so the pole was pulled into an upright position and secured. The boys were really keyed-up so we tried our skill on one of the 65 foot poles. It went up beautifully, and hardly a sweat! Shortly after we got the second pole in an upright position the other mob came, so off we were grunting and pulling with a snort now and then and finally got the third pole up. Three poles were up and it was just a little after 11 o'clock in the morning. As far as I was concerned we did pretty good so I told everybody to knock off for a while to rest. Usually the natives are only too ready to knock off from work, but this time one of the tribal leaders said that the men would rather work since they were all loosened-up. It was unanimous that they wanted to finish the job and go home. Surprised, but slyly happy, I went over to the big 85 foot pole and tied the rope at about the 65 foot mark. The natives were a little suspicious whether we would be successful in raising that pole (I could feel the unrest), but most of them were too proud to "chicken out." I suppose that I felt the same way. Everybody lined up and ready, I gave them the go-sign and with a big shout everybody heaved and began to ease up the pole. It was amazing how easily the pole went up, but then we hit a stand-still. When the pole was raised to a 45 degree angle all progress stopped. We pulled and shouted, pulled and shouted again, but we couldn't budge the pole. This went on for about a half an hour. Actually, it was then that I seriously doubted whether we were going to raise the pole. Sort of disgusted 1 told the men to secure the "X" supports and tie-up the rope to a stake. Then we rested for a few minutes and got our breath. In the meantime I went around among the natives and told them of the story how all the kids raised a pole while I was staying at the Fatima College QTH. I guess I rubbed the fur in the wrong direction with that school-kid stuff, because everybody went to the pole and lined up and were waiting for me to give the sign to heave. Man, you should have heard those natives shout, snort, grunt and wheeze! Those fellows dug in and raising the pole was like letting it fall. The pole was

then straightened and secured. All the poles were ready. Everybody was feeling good, they had a right to, since this was a tough job, and most of all, nobody was hurt. After a job well done I paid everybody. The total cost was \$10.00 and a carton of smokes.

But the job was not finished yet. We had to string up the antenna. I suppose that I could have had the wires and insulators mounted before we raised the poles but I was afraid that things would get tangled and the ropes on the pullies would run off the wheels. I didn't like the idea climbing an 80 foot pole without any climbing gear so I asked for volunteers. For a while I thought that I was going to get stuck with the job, but my bossboy shyly stepped forward and volunteered. Why he was so shy about the whole business beats me. In a matter of about a half an hour that fellow shimmied up those four poles, tied insulators and pulleys, and fed the nylon cord through the pulleys as if it were nothing at all. He and I were good friends from then on. A guy like that is valuable if a pulley jams on an 80 foot pole.

After that we spread out the rhombic, then we went to the feed point and tied in the feed-line and hoisted up the ladder-like outfit. Finally we went down the side of the hill and wired in the terminating resistor (a blob of carbon resistors soldered in parallel, series, and any other way possible). Up went the terminated end, and the pulley ran smoothly. Everything was tightened and the rhombic looked beautiful. I finally had my rhombic!

Since it was nearly sun-down and time to turn on the power, I made a mad dash to the shack and made the necessary connections. After having fired-up the generator, I came back to the shack and tuned up the HT-37. It took me a while to fiddle with the Johnson match-box, but it was worth it. The SWR at the feed-point was 1 to 1! I then tuned around on "20" and heard KC6BK, old Stan from Ponope. Excitedly. I zeroed in on Stan's frequency, switched over to vox control and shouted,

"Break, Stan!"

"Man, who is the breaker?", replied Stan. I was able to feel that Stan was surprised, so elatedly, I answered,

"VK9TG, Stan. How copy?"

"How do I copy! What did you do? You sound like you are running a kW."

Man, I felt like a guy with a brand-new 40 element beam for "20"!

That's when all the DX-ing started, Good old Minj—the best DX and rhombic location a ham could have. ... VK9TG

SINPO and SINPFEMO

It seems that the old faithful RST system of signal reporting is questioned quite regularly as to its effectiveness in communicating the desired meaning. As we all know, it is capable of communicating only three elements of information—those pertaining to readability, strength and tone. However, because of the general laxity of its use, the RST report seldom conveys any useful information at all.

You CW operators look back over your log for the past few weeks of operation. You will find (unless you have an extremely strong signal or an unusually weak one) that over half your received signal reports were 579. When I receive a 579, it conveys a single bit of information to me: "I am too lazy to carefully examine your signal and give you an accurate report; therefore, I am taking the easiest way out." This same fellow who gives you a 579 report can turn around and lose you completely on your next transmission! Strange, isn't it?

Let's take a close, objective look at the three elements of the RST system, and see how our amateur fraternity is using them.

R-readability. The average ham, even while digging through several layers of interference to copy you, will give you an R-5 if he can copy as much as 75% of your transmission. If he copies less than 75%, but more than 50%, you are R-4. If you are practically unreadable, he will give you an R-3 report.

S is for strength. About 95% of the S reports on CW fall within the range of S-6 to S-9.

Hams are just too friendly to come right out and say, "You have a weak signal." This situation points out that the old five-point (S-1 to S-5) scale was better, since the five levels of that scale were generally used. We could go back to the old five-point scale at the present time simply by subtracting four from the present S reports. Thus, most reports would become translated to the range of S-2 to S-5.

T stands for tone. Most ham signals originating from the USA today are either T-8 or T-9. Since few hams realize the stringent requirements for a T-9 signal, all of these T-8 and T-9 notes get grouped in the T-9 category. If a ham has a signal like a buzzsaw going through ten-penny nails, he might get a T-7 or T-8 report. Again, hams are too good-natured to come out and say, "I have heard better notes come out of a soprano saxophone with a split reed." So for all the use it gets, the T might just as well be dropped from the RST system.

The above comments pertain to normal operation. There are two cases which lead to slightly different but equally consistent RST usage—contest operation and reports to DX stations.

During contests, most CW reports are either S-7 or S-9, with R-5 and T-9 reports in all cases. One ham told me he gave *everybody* a 579 report during contests, and I'm sure he isn't the Lone Ranger.

When working non-rare DX stations, ap-

Fig. 2—SINPFEMO reports for phone operation.

proximately two points may be added to each element of the RST system (i.e., a domestic 347 signal is identical to a DX 569 signal). For rare DX stations, this increases to four added points per element. If the reporting station does not have a QSL from the country in question, another two points may be further added to the S scale, and an X appended to the tone report.

Now that we have made this studied analysis of the existing situation, and have discovered the fallacies in RST usage, let us take an objective look at the hams' need for reporting. As mentioned before, the quality of most ham signals today is very good, with either no defects at all or slight, unobjectionable ones. Because of this, there is no need for commentary on signal quality (i.e., note) in the normal report. Rather, it should be commented upon as an exception, whenever necessary. The primary purpose of the report then is to communicate the factors related to the copiability of the signal—the signal strength, the readability, and any reduction of readability due to interference, noise or propagation disturbance.

A system of reporting that meeting these requirements was proposed in London away back in 1953 by the Comité Consultatif International Radio, in their recommendation number 141. This recommendation was for the SINPO reporting code for use with CW signals. This system covers Strength, Interference, Noise, Propagation disturbances, and Over-all readability-each on a five-point scale Further, the CCIR proposed simple one-word definitions of each point of the scale, rather than the long explanations of the RST system. The SINPO code is shown in Fig. 1. The advantage of the SINPO code is that it not only tells you what your signal strength and readability are at the receiving stations, but what type of degradation is present.

The comments thus far have pertained primarily to CW operation, although many of them can be applied equally well to phone

operation. One exception is the signal strength reporting on voice. A report of "sixty dog biscuits over sugar niner" means, "I have a meter attached to my receiver with a very wide scale and markings up to 80 or a hundred on it." Some of the more forward-thinking receiver designers are considering S-meters with scales starting with S-9 at the meter zero point, and divisions at 25 dB intervals, up to 500 dB above S-9.

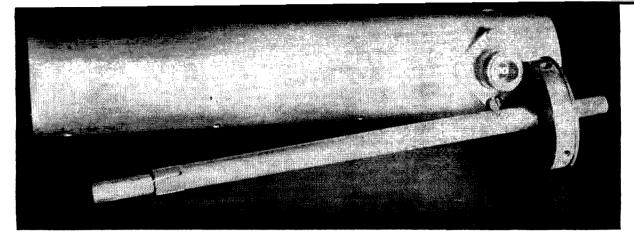

In any event, the CCIR did not forget phone operators in their recommendation number 141. They provided the phone men with the SINPFEMO signal-reporting code. This system covers Strength, Interference, Noise, Propagation disturbance, frequency of Fading, modulation quality (E) and depth (M), and an Over-all rating. The rating scale is shown in Fig. 2.

The SINPFEMO code provides all the advantages of the SINPO code, plus the ability to comment on modulation quality and depth—something that has long been needed in phone reporting. It is to the operator's advantage to keep his modulation quality high and percentage of modulation as near 100% as possible, and a SINPFEMO report would help inform him how successful he is in maintaining an effective phone signal. Such a system is especially needed on the VHF bands, where modulation is generally of poorer quality than that of the average high frequency phone station.

A few months ago, I received an SWL card from what was obviously a brand-new and self-taught short-wave listener. His signal report was a carefully thought-out and critical one based on the SINPO code. It won't take this young squirt long to join the conformity that is amateur radio and start giving 579's to all CW stations (for the short time he continues to use this bourgeois mode of transmission), and multitudinous dog-biscuits to all phone stations.

Me? I enjoy being a non-conformist!

432 MHz Antenna Filter

The 432 antenna filter unit shown in the June 1966 issue of 73 magazine functioned all right on low power and for receiving, but tended to drift in tuning with high power transmitter service. This single tuned coaxial 432 MHz cavity should have an unloaded O of about 4000 and when loaded down to a working Q of 40 or so, will have quite lowloss (a fraction of a decibel). The detuning with from 100 to 150 watts of carrier on phone and 300 watts or more on cw going thru it produces very little effect. The heat loss is quite small. The photograph shows an unassembled line with the inner variable length line and shorted end piece lying in front of the outer shield. It is a quarter wave line which can be adjusted from 6 inches to over 7 fnches in length to tune the cavity to exactly 432 MHz. All copper and brass tubing was silver plated.

The outer tube was made of brass 1% inches in diameter and about 8 inches long. Two coaxial type N fittings were mounted about one inch from the shorted end. A piece of number 12 wire about 1% inches long, bent into a flattened loop, connects from the center connector back to one of the type N mounting screws on each fitting. The 12 wire was made to parallel the inner conductor of the coaxial line but not touch it. Two % inch diameter holes in the outer shell permits some adjust ment of coupling by shoving vigorously with a small screwdriver against the coupling loops.

The inner line was made of % inch OD material, rather thick walled with saw slots in one end. The other end was silver soldered into a piece of 1/16 inch thick brass which had been turned down to a snug fit for the large outer pipe. This inner line extends up about 6 inches from the brass end plate. Originally the end piece was drilled and tapped for

three 6-32 mounting screws. Later it was modified to have 6 mounting screws. This whole unit was silver plated also.

The adjustable line was about 5/16 inch in diameter and about 8½ inches long. It makes a nice snug fit inside of the ¾ inch diameter section with a friction bearing from the slightly pinched-in ends of the saw slots. This is the rf connection and is near the high voltage end of the quarter wave circuit where the current is low. This adjustable line was also silver plated heavily. It is adjustable by pushing or pulling the rear extension part. The outer large section should be more than a quarter wave long and acts as a coaxial shield around the tuned inner conductor. The actual resonant length of the inner conductor will be about 6¾ inches long for 432 MHz.

The filter should be connected into a 50 ohm coaxial line at the antenna side of a coaxial antenna switch. This puts it into the circuit for both transmitting and receiving. The input and output links should be long enough to load the filter circuit to some value of Q=30 to 80. This means good attenuation of undesirable signals outside of the 432 MHz (narrow band generally used).

The loading as well as resonant length adjustment can be made with either a transmitter or receiver. The length is set for maximum signal from the antenna into a 432 MHz receiver. The link coupling is adjusted to give minimum loss when the filter is in the antenna feeder as compared to no filter. A good SWR-power meter can be used with a transmitter to make these same adjustments as a double check. Measure the forward power into and out of the filter and also the SWR at both points. These pairs or readings should be practically identical with a well designed SWR meter in these tests. . . . W6AJF

Six Meter Final Amplifier

Get up to 75 watts output on six with a few watts input.

So many final amplifiers built today are complicated and difficult to adjust. The unit described here is very straightforward and extremely simple to construct and put into operation in your station. A few watts of CW input will give about 75 W output in class C service.

The final tube used can be either an 829B or 5894. The latter is easier to use on 50 MHz as it needs no neutralization. This is a prime factor for selecting the 5894 as neutralization can lead to the crazy house long before perfection is achieved! The bias is obtained by rectification of input power, and the 6BQ5 clamp tube protects the 5894 if drive disappears.

Layout is not critical and can be arranged to suit you. The clamp tube can be mounted under the chassis if necessary. I built my amplifier on a 7" x 11" x 3" chassis. This allowed

Bob is a professional organist. He's worked for the past seven years for the Holiday Inn motel chain. He was once associated with the VHF Amateur and was CQ's VHF SSB editor.

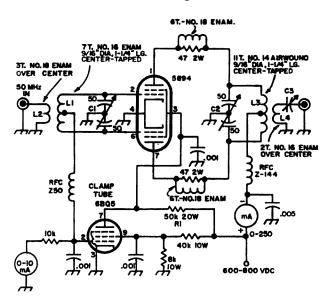

Fig. 1. 5894 six meter amplifier. The same basic circuit can be used with an 829B (or 3E29), but some changes will have to be made in the coils and resistors.

ample space for the power supply at the rear with the amplifier placed up front. It was then mounted in a regular 19" rack panel but could be placed in a cabinet for table top use.

The grid components are mounted underneath the chassis and the plate components are above so that no interaction between the two occurs. The plate coil and capacitor is mounted up front on the panel with the grid components behind the 5894 as viewed from the front. A long phonelic rod is used to connect the grid tuning capacitor to the front panel so all tuning can be done from the front. An alternate method would be to mount the grid tuning capacitor on the chassis so the shaft would be accessible from the top of the chassis directly behind the 5894. The 6BQ5 is mounted to the left and behind the 5894. This allows for short leads between the two tubes.

After construction, insert the tubes and begin checking the unit by using a grid dip meter to set the resonant frequency of the coils and capacitors. Adjust the maximum dip at 50 MHz for both capacitors. At this time, apply filament voltage and check to see that both tubes are lit. Apply plate voltage only after making certain that the unit is connected to a dummy load and the exciter has been connected at J1. Then apply plate voltage and no excitation. The 5894 should draw approximately 20 to 30 mA. Begin loading with loose coupling to the antenna. Apply full grid drive to 5894 and dip the final loading control, C2. Adjust coupling for a plate current reading of approximately 180 mA full load with a plate voltage of 600 V. If trouble is experienced in obtaining these readings in standby condition due to the value of B+, adjust R1.

When using the amplifier on any mode of operation, the clamp tube will be a vital asset as it will always protect the 5894. The setting of R1 in the initial tune up procedure will limit the 5894 to draw only 20 to 30 mA with "key up" condition. This is ample to cut the tube completely off and allow for a safe and sane operation of your new final amplifier.

Have fun in your construction and enjoy its ease of operation and the terrific results for such little effort. . . . K9EID

JANUARY 1967 65

The Drake 2-NT CW Transmitter and 2-C Receiver

When the new Drake 2-NT transmitter and 2-C receiver arrived the other day, I had to rush right home and hook them up to an antenna. I have a base-loaded multiband vertical on 80 and 40, so I didn't know how well I'd be able to work out. After a quick perusal of the excellent instruction books, and connecting them together for semi break-in CW, I was all set to go. A quick three by three call on the 80 meter novice band netted three callers up and down the band; a WN1, a WN3 and a WNØ. I called the WNØ and asked the others to QRX. It turned out that the WNØ was out in Colorado and had never even heard a station from New Hampshire. After exchanging reports we had a nice little rag-chew at about 13 wpm. The 2-NT held up very nicely with 75 watts input—I was running 569 out in WØland. Next the WN3-nice report from Philadelphia, 589. The WN1 was almost next door, so the 599 report wasn't too surprising. And so it went, nice reports from novices all over the country.

Next I changed the tap on the vertical and tried forty meters. Lots of QRM, but when I found a clear spot, the 2-NT didn't have any trouble at all working out with very nice reports. The excellent sensitivity of the 2-C picked up the weak ones and the selectivity took care of any adjacent rock crushers. Then up to 20, 15 and 10. For these bands I plugged in a VFO so I could move around a bit, connected up the tri-bander and looked

for some DX around 14010. I heard lots of Europeans coming through; a short call to a PAØ in Rotterdam resulted in a 559X report followed by several stations calling from DL, SM and OZ lands. After cleaning up the minor pileup, I moved up to 15—same story in Africa. Some nice reports on the 100 watt signal from ZS6 and 5A3 stations. By this time it was pretty late in the evening so ten meters was pretty well closed down; I didn't hear any stations on CW, and very few on phone. Perhaps some other time.

After using the 2-NT for several hours, a few of the hidden features that aid in operating ease become apparent. Basically this transmitter is no different from many other low power CW transmitters; however these hidden features make all the difference in the world. Essentially, the transmitter is a three tube affair, with a crystal oscillator, driven amplifier and final power amplifier. The driven amplifier output and power amplifier input circuits are broadband tuned circuits that are factory adjusted, so no tuning is required by the operator. The pi-network in the output of the power amplifier is designed for 50 ohm coaxial lines, and the loading of this network is also factory set. All the operator has to do is turn the rig on, tune the plate tuning capacitor for a dip in plate current, adjust the power set for the desired power input, hook up the antenna and go on the air. And, if you don't want to tune for meter dip, you can

tune for maximum brilliance of a built-in neon bulb. Operation is simplicity in itself and it takes longer to read about it than to do it. In addition, no external antenna changeover relays or receiver muting switches, no added TVI filters or "harmonikers"; they're all included inside the 2-NT!

The 2-NT transmitter uses grid block keying and extremely clean, crisp CW is obtained by a special pulse and delay circuit. Additional features of this circuit are afforded by the relay which it controls. This relay switches the antenna from transmitter to receiver, mutes the receiver, turns the sidetone off and on in time with your keying and grounds the cathode of your VFO if you use one.

A built-in transistorized 900 Hz phase shift oscillator generates a sidetone which may be used for monitoring your keying. There is a connector on the rear of the 2-C receiver for the sidetone signal; on other receivers it should be connected to the arm of the audio gain control. With these connections, the receiver works normally during receiving, but when it is muted for transmitting, the sidetone comes through the phones. In addition, when the transmitter is placed in the standby position, the 2-NT may be used as a code practice oscillator in conjunction with the receiver. In this mode, the key only controls the sidetone oscillator; none of the other stages are energized.

Another operating aid is the spot switch. With this switch you can spot the frequency that you are operating on without transmitting a signal. It is always good operating practice to listen before transmitting, and the spot switch on the 2-NT allows you to do just that. Only the low power frequency determining stages are energized during spotting, no power is applied to the final stage.

All in all, the 2-NT transmitter is one of the easiest to operate that I have ever used. All the controls have a purpose, and all the set and forget type controls have been adjusted at the factory. In addition, no accessories are necessary to put an outstanding signal on the air. For the novice, the 2-NT appears to be an ideal starter transmitter; even many generals will find it to their liking.

The Drake engineers really put their heads together when the 2-C receiver was on the drafting boards. What they have come up with is a neat combination of vacuum tubes and transistors that does a tremendous job. Vacuum tubes are used throughout the amplifier, mixer and if stages, but transistors take over in the high frequency oscillator, detector, BFO, AGC and audio stages. A total of five tubes and seven transistors do the bulk of the job; along with eight diodes for detecting and rectifying duties.

The rf lineup is relatively straightforward; a 12BZ6 rf amplifier, a 12AU6 high frequency mixer, two 12BE6 converters, and a 12BA6 50 kHz if amplifier. The two inputs to the high frequency mixer consists of the output of the rf amplifier and the output of the 2N3394 crystal oscillator. The output of the mixer stage is 3.5 to 4.0 MHz. This 80 meter signal is mixed with a 3955 to 4555 kHz VFO in the first 12BE6 for a 455 kHz if output. The second 12BE6 converter accepts either a 405 or 505 kHz input to put a 50 kHz upper or lower sideband into the 12BA6 if amplifier. A 50 kHz bandpass filter in the 12BA6 input provides an adjustable passband selectivity of

Drake 2-C Specifications

Frequency 3.5-4.0 MHz, 7.0-7.5 MHz, 14.0 coverage: -14.5 MHz, 21.0-21.5 MHz and 28.5-29 MHz with the crystals

provided. Accessory crystals will cover any 500 kHz segment between 3.0 and 30 MHz.

either 400 Hz, 2.4 kHz or 4.8 kHz at the 6 dB points.

The sensitivity and selectivity of this lineup is really tremendous. The 0.5 µV sensitivity for 10 dB signal plus noise to noise on all bands from 80 through 10 really pulls in the weak ones. Like the old adage says, if you can't hear 'em, you can't work 'em. And after a few minutes warm up, the drift is not detectable; even with a 10 volt change in line voltage the drift is only barely perceptible. When a strong local comes on the 2-C performs admirably. The 12BZ6 contributes a great deal to this because of its low intermodulation characteristics, but the variable passband filter does most of the work. When the going really gets rough, you can turn it down to the 0.4 mark; in this position the bandpass is still only 2.7 kHz wide 60 dB down.

The amplified AVC systems works extremely well. When the stations are weak, there is almost no AVC voltage applied to the rf and if stages, but let a strong signal come on and immediately it is at a comfortable listening level. In fact, there is less than 6 dB audio change for a 100 dB change in rf level. To give you an idea what this means, 6dB is about the difference between programming and commercials on TV; 100 dB is the same as comparing a 1 watt transmitter to a ten trillion watt transmitter; for different types of operation, the operator may choose slow or fast AVC release times, or he may turn the AVC off.

The 2-NT transmitter and 2-C receiver, working singly or as a pair provide an extremely convenient and economical starter station for the novice. And when the novice advances to the general ticket, many will find that this equipment is still ideally suited to their needs. For ssb and RTTY operation, the 2-C stands up right along with many of its more expensive cousins, so when the general ticket arrives there is no need to go out and buy another receiver. For portable or field day operation the pair is ideal. They are compact, easy to tune, require a minimum of outside accessories and require a minimum amount of power; perfect for low power gasoline genera-. . . W1DTY tors.

Space Age Soldering

1 read K4CPR's article in the March 73 and it inspired me to look up the methods for space vehicle soldering. When you are putting equipment into orbit every solder joint must be perfect. This is how it is done.

Given-a cruddy old resistor to solder into the circuit.

- 1. The part to be soldered is never handled with the bare fingers. This puts oil where you want the solder. You use a pair of gloves or nylon finger cots when touching the leads.
 - 2. Choose a soldering iron:

Wire gage 20 and smaller 35 watts Wire gage 20, 16, 14, 12 50 watts Wire gage 12, 10, 8, 6 100 watts Wire gage 6 and larger 200 watts

- 3. Take a pink pearl eraser and shine the area to be soldered.
- 4. Dip a brush in trichloroethane, or equivalent, and wash the area to be soldered.
 - 5. Take another brush and coat the area to

be soldered with liquid rosin base solder, MIL F 4995.

- 6. Heat the iron, dip the tip in liquid rosin flux, apply solder to the tip of the iron, and wipe it clean on a damp cellulose sponge.
- 7. Tin the lead to be soldered by putting a heat sink next to the body of the resistor, apply rosin core solder to the iron tip, and within six seconds apply the solder to the wire for five seconds only. If you are not able to apply the solder within six seconds, wipe the iron clean and start with fresh solder.
- 8. After tinning the lead solder the part within an hour. If this is not possible wash off the flux with trichloroethane and reflux when you are ready to solder. After soldering the connections wash off the flux with a brush and trichloroethane.

If you follow the directions you'll find they work just fine but I find a good sprinkling of profanity to be of great service.

. . . Del Wininger WB6JNI

A Simple Voltage Calibrator

Are your meters lying to you? Most likely they are. In this article Jim discusses the causes and results of meter errors, and shows how they can be overcome.

There is a remarkable likeness between the archer who is aiming for his target and the amateur designer who wants to design a circuit. Both follow a procedure which is only partly based on clear, sharp textbook theory. Each depends heavily on intuition, on accumulated habits derived from previous successful experience. The archer who practices with crooked arrows can only hope to succeed in an average sort of way, with many discouraging events to try his patience and interest.

Not all instruments are accurate. There are various kinds of inaccuracy, and as with other machinery, the properties of instruments tend to drift with time. Calibration may also be violently altered by laboratory accidents. Suppose two meters which once behaved identically no longer do so. Which is wrong? Could they both be wrong? It appears that a third party, rather isolated from the usual events of the lab, is required. This article describes a sort of secondary voltage standard, very good in proportion to its cost and effort of construction.

Some notes on meters

The problem of meter calibration is best viewed against a brief background of some facts about meters. Further perspective devel-

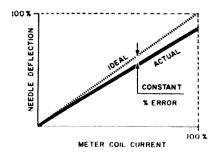

Fig. 1. Performance of a wrongly calibrated but linear meter.

opment would result from a review of material appearing in handbooks and textbooks.

It may come as a surprise that all moving coil meters are current-sensitive devices. They do not respond, except indirectly, to voltage. They appear, sometimes, to respond to voltage because of the constant influence of Ohm's Law upon the circuit, but in fact they are only indicating the current passing through them. This is because each meter movement contains, as an integral part of itself, a fixed magnet. A coil moving in the magnetic field experiences a force proportional to the current passing through the coil. Voltage does not produce a magnetic field as does current, so that conventional meters respond to current, not voltage.

Another valuable point will appear upon close examination of almost any multimeter, de ammeter, or other indicating device. It is the fact that the scale is linear. That is, the angular deflection is directly proportional to the applied voltage or current. The divisions across the scale are equally spaced and each one represents the same increase. By contrast, an ohms scale on the same meter will be nonlinear: the range from zero to five ohms at one end may take up as much scale space as 200 ohms to infinity at the other end.

Meter manufacturers are very interested in linear meter movements. Design and calibration problems are simplest if a linear scale can be used with a linear movement since only a single adjustment is required to calibrate the entire instrument. This is the common full-scale adjustment, a simple calibration performed to bring the full-scale reading into agreement with the full-scale voltage or current. The manufacturer wishes to produce thousands of similar meters with least expense and effort; the user would like to check the entire calibration with one measurement. This is not possible if the meter response is curved,

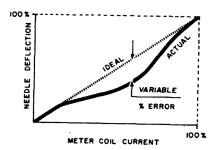

Fig. 2. Performance of a "rightly calibrated" but nonlinear meter.

since then the degree of curvature has to be measured, a much more complicated business than a single point calibration.

In 1882, D'Arsonval called attention to the virtues of a certain type of meter movement which combined durability, simplicity, linearity, and relative immunity to outside effects. It is now known by his name, and is used in virtually all meters made. This movement is mentioned in many publications, described in a few, and is very well worth looking up. An old pre-1900 physics or science book will yield surprising and interesting information on the elaborate predecessors of today's apparently simple multimeters.

Meter error

There is no such thing as a perfectly accurate meter. The readings of a particular meter may be accurate, for instance, within 10%, 3%, or 0.5%. The price rises rapidly as the accuracy improves, but there is no meter at any price without error. In order to keep the picture simple, the source of the error can be neglected, and reference made only to the reading observed on the meter together with its dependence on the applied current. Then the observed error can be broken down into three types: stiction, calibration error of a linear meter, and linearity error of a "properly calibrated" meter.

Stiction is observed in this way: you place the probe in the circuit and observe a reading. Without disturbing anything else, you tap the face of the meter with finger or a pencil; the reading creeps upwards slightly. The explanation is sticky friction: you can experience much the same thing by sliding your hand along a smooth surface. If it moves in a series of starts and stops, that is stiction. Another example is the peculiarly unpleasant way in which fingernails slide along a blackboard. Obviously this has no good function in the meter's bearings and much effort is made to eliminate it. Particularly in the less expensive meters the effort may not be so successful. Sometimes a read-

justment of the meter bearings will improve the situation: this is very, very much like gambling, if you're not an expert. When making accurate readings, always assume there is some stiction and tap the meter face or the panel nearby. Use something light and don't overdo it.

There is a sort of relation between calibration error and nonlinearity. The separation made here is for purposes of explanation, and in any discussion of one the other should be assumed just offstage, waiting eagerly for an opportunity to make an unobserved and frustrating entrance.

Fig. 1 shows what is usually meant by calibration error. We assume that the meter's characteristics are strictly linear. That is, that a 1% increase in current through the meter produces a certain swing of the needle which is the same anywhere on the scale, and the swing is through an angle just 1% of the total swing from zero to full scale. That means the meter's characteristics will plot out as a straight line, shown as a dotted line labeled "ideal". The solid line labeled "actual" shows the performance of a meter with a calibration error. This kind of calibration error is usually corrected by a trimmer device added somewhere in the immediately adjacent circuit.

Fig. 2 shows what is meant by nonlinearity error. Note the full scale reading is just what it ought to be. Zero is also where it belongs, but there is a rather irregular deviation above or below the ideal between these extremes. When you have finished the Calibrator, you will very probably find this type of error in at least one of your instruments. If this error appears in a vacuum tube voltmeter or its solid-state equivalent, perhaps it can be reduced by a trial-and-error interchanging of tubes or transistors.

It is important to retain a correct perspective when dealing with calibration problems. A diagram like Fig. 3 is very useful, because it shows that a deviation of perhaps one tenth volt can be a large error at the low end of the

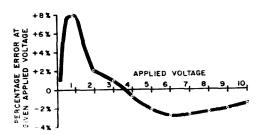

Fig. 3. Performance of a popular multimeter as measured with the Calibrator. Note unexpectedly large error at the low end of the scale.

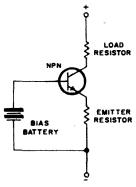

Fig. 4. Skeleton circuit of the Calibrator.

scale and a trivial error at the high end. Calibration and linearity checks will be most meaningful if plotted in this way. This curve was derived from a real instrument, a popular multimeter priced at \$16.88.

Calibration using fresh batteries

It's popularly believed that fresh batteries can be used as accurate calibration voltage sources. This is partly true, but it is not true enough to meet modern requirements. The reproducibility of electro-chemical reactions and the similarity of one production-line item to another seems to imply that two batteries from the same manufacturer or even from two different manufacturers ought to be as like as two peas in a pod. Or at least that such differences as appear ought to be in some respect other than terminal voltage.

But differences do appear. Some policy has to be adopted permitting important differences to be weeded out from insignificant ones. Microvolt differences are clearly unimportant; differences of a tenth or a half volt clearly cannot be tolerated if batteries of around 1.5 volts are going to be used for calibration standards. It seems reasonable to suppose that for general-purpose work, a calibration source should be accurate within 1% or better; that is, at 1.5 volts the extremes would be 15 millivolts each way. A significant factor in thinking about tolerances is the possibility that one calibration may end up at one extreme, and some other calibration at the opposite extreme. An accuracy of 1% does indeed seem to be the upper limit on tolerable error for calibration purposes.

A large number of fresh pencells, standard carbon-zinc D cells, and assorted mercury batteries were tested to determine likely variation in terminal voltage. Variations as great as 50 millivolts were found in cells from the same box. This amounts to a range of nearly 2% each side of the mean voltage for that batch,

and since few amateurs will have a method for determining whether the average is correct or skewed, it appears that the idea of using fresh dry cells for calibration purposes has been exploded. Perhaps it would be preferable to say the idea has been well undercut; the fresh cells are better than nothing but they appear to be not as good as a serious worker should require.

Calibrator circuit theory

This calibrator uses an unusual method for generating its output voltage. In most such devices, a voltage-determining circuit feeds the output directly, or is followed by some resistance-divider device to generate the variable output. This is a simple scheme, basically, but it suffers from a significant shortcoming. Calculation of the change in voltage due to load tends to be difficult, because there is no simple way to estimate the properties of the standard at most settings.

If the electronic circuit is designed to standardize a current rather than a voltage, Ohm's Law and the resistor manufacturer's engineering tend most reliably to the conversion of the current into a voltage. Computation of the error due to passage of some of the current into a load circuit becomes very simple if a wise choice of circuit parameters is used. In the case of the Calibrator, a constant current of 5 milliamperes is supplied to a 2000 ohm potentiometer. high-quality ten-turn thousand-point scale (one hundred points, per turn, ten turns) thus cranks out 2 ohms per division from zero, and the voltage across this resistance is just that produced by 5 milliamperes less whatever current is delivered into the load.

The basic circuit of the Calibrator is shown in Fig. 4. A voltage reference source and a transistor fix the voltage across the resistor R. The transistor acts as an emitter follower. Since the voltage across R is fixed, the current through it is also fixed. The same current flows

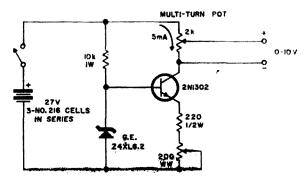

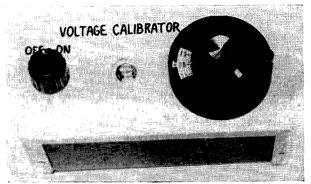

Fig. 5. Complete circuit of the Calibrator. Most of the parts are completely uncritical.

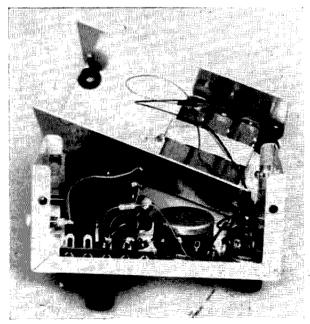

The finished Calibrator. The dial reads 2.20 volts. Adjustment for accurate output by screwdriver pot in the center of the panel.

through the load resistance that serves to convert the current into a voltage.

Fig. 5 shows the complete circuit, hardly more complicated. The resistor in the transistor emitter circuit is split into one fixed and one variable resistor, to permit vernier adjustments in current. The transistor base voltage is fixed by a zener diode, and a resistor has been added to supply the necessary zener current. A non-critical battery and a switch complete the circuit.

The voltages across the circuit have to add up to the battery voltage. From the battery to the zener biasing resistor, down through the zener to the other terminal of the battery, is the complete biasing circuit. Since the transistor has a beta of 100, it draws negligible current from the zener. It is only necessary for the zener to be safely out of its knee region; but not too far because current in this

Inside the Calibrator, showing point-to-point wiring.

circuit loads the battery with no return in

The other current route is down through the load resistor, the transistor and the emitter resistor. Since the voltage across the emitter resistor is fixed by the transistor, the base-emitter voltage remains fixed at about 0.2 volts, and the voltage across the load resistor is fixed by the constant current through it, the only voltage that can vary as the battery ages is the transistor collector voltage. But collector voltage variations have practically no effect on transistor current. So long as the transistor remains within its operating range, the circuit works.

There are some nearly invisible secondorder effects. The only one worth mentioning is a slight drift over the first few seconds after the Calibrator is turned on, due to the zener and the transistor warming up.

Calibrator construction

There is nothing critical about layout and construction. For best results, new parts are preferred, but junkbox or surplus parts should yield perfectly good results in all cases where you are properly suspicious and apply careful tests to the components. Since this circuit is a little bit odd in comparison to most of those appearing in the amateur literature, it might be breadboarded before construction and a few tests performed to clear up the facts about its performance. A milliammeter and a Diddlebox1 in series with the transistor collector circuit will show clearly that the current is remarkably independent of changes in collector load, so long as the transistor is biased into its operating region.

The calibrator is built in a 2½ x 2½ x 5 inch Premier Minibox. The wirewound calibration pot and the multi-turn pot plus two insulated lugs on a standard lug strip provide enough terminals for point-to-point wiring of the entire circuit. A solid bracket holds three standard 9-volt transistor batteries in the bottom piece of the case; three 8.4 volt mercury batteries could have been used. They hardly seem to be required. The Calibrator is highly valuable when needed, but it does not receive the steady use of a VTVM or a scope.

Two GE zener diodes were purchased for this project, just in case. It turned out that one of them had a knee at around 7 mA; the other at well under 1 mA. This is within specs; they are apparently tested at the factory at 20 mA. The lower current is preferable; the zener

Diddleboxes are discussed in the April 1966 issue of 73, page 48.

has to hold the transistor base voltage only against a few tens of microamps plus the transistor leakage current of a few microamps.

If a zener other than the specified GE Z4XL6.2 is used, an appropriate revision of emitter resistors is very simple: the total resistance should be chosen for zener voltage less 0.2 V base-emitter voltage at 5 mA or whatever other fixed current is chosen.

If a surplus transistor is used, a fairly high beta is preferred, but not over 200 or so. It should show low leakage current; in any batch of ten or twenty similar transistors at least one will show up with good beta and remarkably low leakage. Choose that one. If the emitter resistor takes up six volts and the multiturn pot takes up 10 volts, the rest of the battery voltage has to appear at the transistor collector terminal. In the schematic of **Fig. 5**, this is about 11 volts. Some surplus computer transistors are good for only 15 volts.

Finally, if a surplus pot is used, it should be checked for noise and erratic operation. Put a battery across its terminals at sufficient voltage for a few milliamperes through the potentiometer. Add a load resistor or perhaps 20 k Ω from its slider, and listen with a signal tracer. A slight, almost musical, noise is permissible; erratically noisy regions or spots are grounds for rejection.

Calibration

A few final tests will quickly indicate whether the circuit is operating properly. A milliameter in the transistor collector circuit should show constant current against variations in battery voltage. Placing an additional resistor across the zener biasing resistor for a 10% current increase should have no more than a barely discernible effect upon collector current. Perhaps you can think of one or two other tests.

The calibration procedure is simply a matter of adjusting transistor current through the multiturn pot to the correct value. This may not be quite 5 mA, or it may be a little over, because of the 3% or 5% tolerance on overall resistance of the pot. This tolerance has nothing to do with the 0.1% or better linearity tolerance, which determines the accuracy of intermediate readings. The transistor current is adjusted to give a correct reading at any fixed pot setting, preferably full scale. Unlike many meters, the linearity of the pot is guaranteed, so that the full scale calibration is reliable in this case.

Of the various possible sources of known voltages or accurate indications for calibration purposes, batteries have already been dis-

cussed. A calibration may be performed by comparison with some meter believed to be correct, but this is a somewhat risky procedure. An expensive or a new meter is more probably accurate than an old or inexpensive one, but there is a distinct element of risk that cannot be eliminated when calibrating in this way.

A better and more reliable source of accurate voltage is a standard cell. High school physics laboratories frequently have inexpensive but quite good standard cells available, or one may be purchased from a scientific supply company. They are sealed in glass and last for many years if they are not subjected to overload, extreme high or low temperatures, or excessive vibration. The manufacturer is generally very specific as to what constitutes abuse and his notions should be respected. In most cases, a load of 10,000 ohms is about the minimum; this draws about 100 microamps from the usual approximate 1.0183 volts.

Fig. 6 shows a circuit for calibration by standard cell. The switch is a normally open push switch so that current is drawn from the standard cell only for brief periods. Any 0-50 microammeter will do. To make the calibration, the Calibrator dial is set to the standard cell voltage and locked in place. The vernier calibration pot is adjusted for a barely perceptible upscale deflection of the meter. Then the 4.7 k Ω resistor is shorted out, and the vernier calibration pot readjusted for a zero reading. This completes the calibration. The microammeter reading goes to zero because the Calibrator on one terminal and the standard cell on the other are putting out the same voltage: no current flows if no potential difference exists.

An amateur or experimenter sees a potentiometer as a resistance with a slider supplied in a little case and capable of a few percent resolution. A more elaborate potentiometer, perhaps costing over \$1000, may be found in the high school or college physics laboratory. If one is available, certain accessories required for its use are probably also on the premises, and it may also be used for calibration of the Calibrator. Some reading in appropriate physics texts will be required, but potentiometer theory is not elaborate and you should have few difficulties with it.

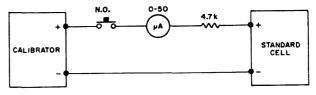

Fig. 6. Circuit for calibrating the Calibrator from a Standard Cell.

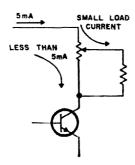

Fig. 7. Loading the Calibrator reduces its output voltage exactly in proportion to the current sidetracked around the multiturn potentiometer.

The very nicest instrument for calibration of the Calibrator is a digital voltmeter, frequently referred to as a DVM. It usually contains its own standard cell, and its design is inherently accurate. After checking the DVM calibration, connect it to the Calibrator, set the Calibrator to 9.95 volts, and adjust the vernier pot until the DVM gives the same reading. Then, just for kicks, crank the Calibrator pot down to various lower readings and watch the DVM produce readings agreeing within a millivolt or two. It's very impressive.

Operation

The calibrator dial reads 0-10 volts in ten turns of 100 points per turn. That is ten millivolts per point, one volt per turn. This direct reading is very convenient! It is the reason for choosing a scale of 0-10 volts rather than 0-5, 0-1.5 or some other range. 0-1 volt was considered, but a ten-volt range seems to be more appropriate for meter calibration and general laboratory work.

Many applications for the Calibrator will demand so little current that its calibration will be inappreciably altered. To achieve a 1% change in calibration, the load must steal 1% of the 5 mA supplied to the multiturn pot. That is 50 microamps. If this current is supplied from 10 volts, the load is 200 k Ω . If the load exceeds 200 k Ω , no correction is required for most applications. For example, an 11-

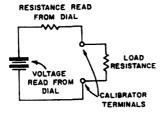

Fig. 8. Shorthand equivalent circuit for quickly estimating true voltage at the Calibrator terminals when supplying current to a substantial load.

megohm VTVM, a backbiased diode test, or a voltage comparison test in which two voltages are adjusted to equality so that no current flows, would require no correction at all.

But laboratory applications are so variable that no guarantee at all can be made as to the size of the load. The key to the problem of working out the calibration change under load rests in the constant current generator. It always supplies 5 mA, or something very close to it. The situation resolves to that shown in Fig. 7. The load current is subtracted from the constant 5 mA, the voltage across the Calibrator terminals must be that due to remaining current through the resistance from slider to ground. This resistance is two ohms per division, since the 2000 ohms of the pot are allocated equally to the 1000 scale points.

Fig. 8 shows an equivalent circuit which expresses the same facts. A generator always supplies the voltage seen on the Calibrator scale. The load current passing through R reduces the voltage to that seen at the output terminals. R is the resistance from slider to ground of the pot. The subject is more fully discussed under Thevinin Generators in many electronics texts: this concept is one of the greatest problem solvers going.

Some suggestions

It isn't necessary to build the Calibrator exactly as described. I've tried to describe it completely enough so you can see what the ideas behind it really are. You can work up your own model which might be very different from mine. Here are some of the variations which occur to me.

A single-turn pot might be used, preferably wire-wound, although 5 mA through 2 k Ω will dissipate only 50 milliwatts so that a composition pot could be used. But in such a case you probably cannot trust the linearity, which greatly simplified and improved my Calibrator. A resistor or a set of resistors could have been used, which would limit the number of voltages available, but would avoid the expense of a multiturn pot. The voltage out or the transistor current could have been chosen at other values, but there are problems here too. If a very low maximum voltage is chosen, you may find yourself involved with thermoelectric effects. If a high transistor current is chosen, you may find, for some applications, more drift than you like resulting from variation in transistor dissipation as the battery runs down. Well, have at it! Make up a breadboard and don't be afraid to try out some new ideas starting where I've finished.

The Link

Like to try a two meter yagi with a semi-cylindrical reflector?

If you are interested in making your "Five Watter" sound like a big rig, then read on.

The "Link" I am about to describe has been the volume producer here for sometime now and I feel that it warrants passing on to the brotherhood at large.

There is no great cost involved, in fact five dollars should cover the Link quite well.

The materials involved are a length of tubing for the boom (the boom from an old TV antenna works quite well) and a roll of aluminum clothes line wire for the elements. The rest of the hardware should be handy around the "shack."

The basic components of the design are by no means new, but putting them together in this configuration I feel is now or at least novel and for good measure it works.

The basic theory behind the antenna is a modified corner reflector used as a launching device for the yagi antenna. An added bonus is the unusual front-to-back ratio gained by this method.

It might be well to add here that if you are

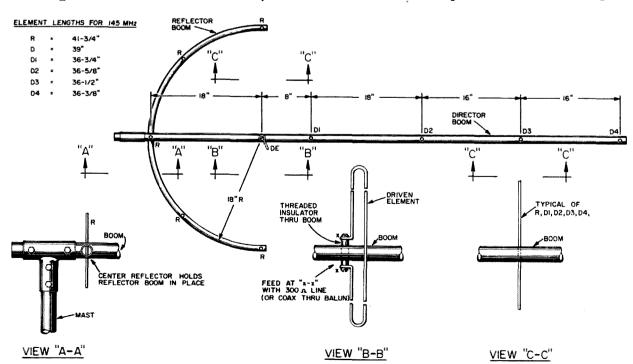

only interested in local rag-chewing in the big cities and don't care to rotate your antenna for each contact, forget it and go on to the next article. This antenna is for the stations that are hard to copy.

The method of mounting the antenna makes it quite adaptable to either horizontal or vertical polarization depending on the locality.

The method of construction should be quite clear from the diagrams, but there are a few things that are hard to show in a drawing such as the method of mounting the boom for the corner reflector part of the antenna.

The boom is first drilled to take the reflector boom. When this is in place then the hole for the reflector element is drilled through both pieces of material and the reflector element set in place. This will then hold the whole assembly ragid.

The next step is the driven element. A hole is drilled in the boom and an insulator that is about one inch longer than the boom is thick is inserted through the boom. This then becomes the anchor point for the folded dipole

driven element. The beam is also fed at this point, either through 300 ohm line or with a balun

As for tuning the antenna, well if the beam is constructed using the measurements given I think you will find little if anything gained by shifting the elements. A bit might be gained by clipping the elements for spot frequency operation, but that's up to you.

The tests given this antenna were with a fellow ham W6RGG across the valley from my location about four airline miles away.

The test equipment used for this evaluation? A "Gooney Bird" and a receiver with an S meter. The antenna was mounted on a thirty foot mast and pointed toward the receiving location, the rig was turned on and a steady tone was used for modulation.

The S meter at the receiving location was set for twenty over nine, then the antenna was rotated. The main front lobe seemed to be about thirty degrees wide. The side lobes showed a reading of S2 and the back was all but unreadable on the meter.

A word about the mounting feature. It may seem at first glance that the beam will be off balance, but in practice it has been found that with the beam so light and the advantage gained by this type of mounting there is nothing to fear.

I can only hope that those of you who construct this antenna get as much enjoyment out of it as I have had.

Stop Slipping Dial Drives

Does the cord and pulley dial drive system in your receiver slip occasionally? If so, here's a good emergency substitute for cake rosin or commercial non-slip compounds.

Place the tip of a hot soldering iron or gun on a clean area of the chassis and tilt the iron so that the tip forms a small angle with the chassis. Feed rosin-core solder into the gap. The cold metal of the chassis will conduct enough heat away from the molten solder so that the flux, instead of vaporizing, will form a "puddle" on the chassis. Remove the soldering iron, allow the flux to solidify and scrape it onto a clean piece of paper. Finally, crush the flakes of flux with a fingertip and rub the resulting powder onto the dial drive cord.

Some Techniques in Tone Signalling and Decoding

Tone signalling has many uses in ham radio, especially in VHF emergency and other nets. This article describes a few things that should be considered in using tones.

It is perhaps time to admit that the manufacturers of citizen's band equipment have in one respect gotten a bit ahead of amateur radio progress. Amateur RTTY operators have for sometime used various "auto start" systems to good advantage, but the typical amateur hasn't really put to much use any automated transmission start-stop system such as is presently employed by many CB two-way stations.

Naturally, in the course of everyday operation the typical ham doesn't have much need of the system described here, but increasingly more amateurs are going to remote operated equipment to obtain better advantage of physical surroundings. Although the authors cannot vouch for the legality° of operating such a system, it seems reasonable to assume that an amateur could operate his home station by remote signals from his mobile station. This would allow any non-amateur in the home to speak with the mobile station, since the home station would in effect be directly controlled by the mobile station and hence under the direct control of a licensed amateur. The pos-

o It is likely that the operation described might require a remote station authorization. Check before you try it,

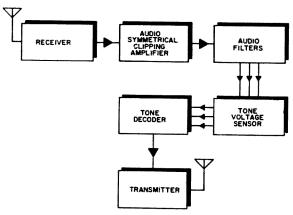

Fig. 1. Block diagram of a tone signalling repeater system.

sibilities of this situation seem very intriguing, particularly in the case of businessmen who must remain away from home for extended periods or at long distances. With the system to be described here, a particular sequence of tones modulating either an SSB or AM transmitter (either A3, A3a or A3j modulation) could be used to trip a receiver, turn on a second transmitter and then turn on or turn off either or both the receiver or transmitter in any prescribed sequence. Similarly a different sequence of the same tones, or different frequency tones, could be used to shift frequency, rotate the antenna or perform any number of functions at the receiving end. The possibilities are limited only by the desire and ingenuity of the operator.

System theory

The system block diagram (Fig. 1) shows the general configuration for the use of the sub-units to be described later. A signal coming in the antenna to a receiver preset to the desired operating frequency is passed onto an audio clipper and amplifier. The purpose of this first operation is to ensure that all the tone signals are of equal amplitude before reaching the audio filter. This not only relieves the filters of the requirement of undue selectivity but also ensures that the output from the audio filters is about the same for all tone channels.

The next block, the audio filters themselves consist of a number (depending upon the number of tone channels used) of simple L-C filters resonated to the frequency of the tone channels. In this article a three channel, and hence three filter, network is described, but again more or less channels and filters may be used depending upon the desired complexity of the end result. Obviously, there is one filter resonated to the tone frequency of each tone channel used.

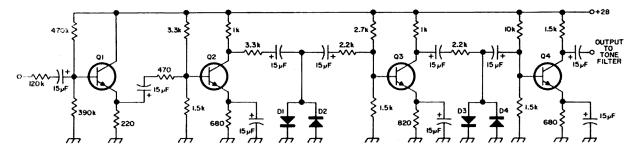

Fig. 2. Symmetrical clipping amplifier. See text for transistors and diodes.

Following the audio filters are the tone voltage sensors, one sensor for each filter, hence one sensor per tone channel. The function of the tone voltage sensors is to detect the audio tone when present at a filter output and convert the tone to a dc level appropriate for driving a switch. This is accomplished by a variable threshold gate and Schmidt trigger arrangement to be described later.

Dc voltages which correspond to the presence of a tone are passed on to a tone decoder which consists of nothing more than a series of relays interconnected in such a way that the sequence of tones received must be in a certain prescribed order before an output is obtained. Certainly more sophisticated electronic switches could have been used in this application, but for purposes of explanation the sequence of operations is perhaps most easily understood when presented in terms of relays. This also lends itself to direct junk-box production by the amateur in most cases.

Connection is shown from the tone decoder to a transmitter, but obviously the piece of gear being controlled might be anything the operator desires, multiple operations or multiple equipment functions can be controlled as pointed out previously.

General

Although each circuit to be described here is complete and correct, the intent is that the circuit function to be detailed is of more importance than the actual hardware of the circuit itself. Consequently, no direct examples are given for building duplicate units though duplicates may be constructed quite easily. Actually there is nothing the least bit critical about construction save that the usual precautions to prevent rf energy from entering the

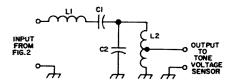

Fig. 3. Tone filter. L1-C1 and L2-C2 should be resonant at the desired audio frequency.

audio stages should be observed. As mentioned previously, the number and types of equipments controlled by this type system is practically unlimited dependent upon the resources of the individual amateur.

Audio symmetrical clipping amplifier

As explained, the purpose of this circuit is to provide a constant amplitude signal to the tone filter regardless of the audio output amplitude of the receiver at any given time. The input to the circuit is a sine wave at the audio frequency, and because of the particular design here, the output is very nearly a square wave of the same audio frequency. Looking at Fig. 2, it may be seen that the input stage is an emitter follower which is biased at about half the B+ voltage. This stage is used simply to provide a high input impedance as well as low output impedance to drive the second stage. This second stage is an amplifier driving a diode clipper. Since the voltage gain of this stage is high (about life x 1k) the sine wave at the collector is heavily clipped by the D1-D2 pair, then passed on to another amplifier and diode pair where the signal is again amplified and clipped. Notice that no type has been called out for in the diodes or transistors: any transistor with life greater than 100 at 1 kHz will surely do, and any good silicon diode will fill the bill. The one and only requirement that must be carefully met is to be sure that all stages are biased in the mid-range of their operating conditions. The "Q-point" must be

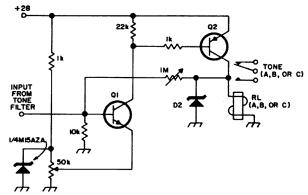

Fig. 4. Tone voltage sensor for use with a tone filter such as the one shown in Fig. 3.

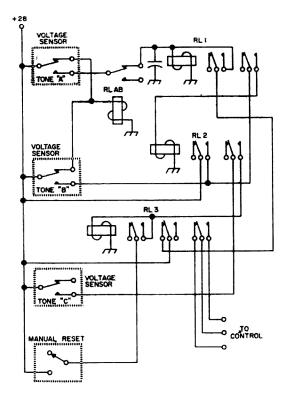

Fig. 5. Typical tone decoder. See text.

set mid-range between cutoff and saturation. This is because a large amplitude signal will cause the transistor to clip as well as the diodes, particularly at Q3 and Q4. Since a clearly symmetrical output is desired, the transistors must begin to "bottom out" and "topout" evenly for increasing input signal.

Tone filters

The tone filters are used to select and pass the individual audio tone frequencies desired. The filter shown in Fig. 3 is about the simplest that is useable. Normally the audio frequencies selected are about 1 kHz apart and thus this simple filter is more than adequate to reject adjacent tone "channels." Certainly a more complex multi-pole filter may be used and the separation between tone channels reduced accordingly, For this filter, L1-C1, and L2-C2 are resonated to the desired audio frequency. As can be seen, with reasonable (greater than 50) Q inductors a fairly high selectivity may be obtained. Ordinarily the output tap on L2 is about \(\frac{1}{2} \) of the coil up from the ground end. For fanatics there are a number of active filters which will provide as little as 1 Hz 3 dB bandwidth at 100 Hz center frequency. However, anyone sufficiently versed in the literature to use such a circuit is probably bored with this article and has quit reading, hence no further discourse is given here.

Tone voltage sensors

This circuit is essentially a variable threshold relay driver with a variable feedback circuit to provide high sensitivity and a certain amount of latching action. Again the active devices aren't specified since so long as good hefty (perhaps 1 watt) transistors with Vce of at least 30 volts are used no trouble will be experienced. Progressive shorting out of the one megohm pot will increase the sensitivity of action, but will also provide increasing hysteresis on signal release such that in the extreme, several volts differential would be apparent between the threshold level and the release level. The threshold level is preset by the 50 k Ω resistor in the emitter of Q1. This preset level is above the noise output level of the tone filter but generally below the maximum tone output amplitude. Notice that the relay is the same as that depicted in Fig. 5.

Decoder

The decoder of Fig. 5 is composed entirely of relays principally because relays are quite often available to the amateur in quantity. However it is obvious that a considerable reduction in size, weight, and generated transient noise could be obtained by use of equivalent solid state switches.

Obviously the simplest decoder would be a single switch which closed upon the presence of a given tone. However such a system would be vulnerable not only to accidental tripping and jamming, but also would be vulnerable to deliberate interference. The decoder shown here is fairly elaborate, but not so involved that construction is prohibitive. In many respects this decoder simulates the function of a "secure" system used by many governments to avoid unauthorized use of equipment and ensure secrecy.

For this particular decoder three tones of differing frequency are necessary (and hence three tone filters, etc.) for operation. The tone frequencies have been labelled A, B, and C for convenience; tone A might be selected as 1 kHz, tone B as 2.5 kHz and tone C as 5 kHz for instance. Due to the interconnection of relays and contacts a sequencing action must take place before the control is actuated. In this case, tone A must occur before tone B, and tone B occur before tone C, and A and B may not occur simultaneously. Hence, unless some random signal or person interested in actuating this system knew the exact tone frequencies and the proper sequence of these frequencies the control would not be actuated. Thus by using the latching properties of only four relays a very "secure" three tone system is available.

[•] For those who wish to pursue this phase of the project, a really excellent article entitled "Selective Audio Amplifiers" appeared in the July Electronics World.

Conclusions

The four basic building blocks described here constitute the prime requirements in a secure tone signalling system. The uses have been briefly described for tone systems, and if nothing else, it is quite apparent that a very good amateur remote control system could be effected in a variety of ways. Each building block is quite uncomplicated, and easy to build and adjust. The authors have implemented this system in a variety of ways, for single tone signalling using one to eighty meter remote to home applications, all with great success. As was stated before, the applications are limited only by the ingenuity of experimenter.

A Low Cost AC Regulator

The detrimental effect that line voltage changes have on oscillator stability is well known by most hams.

A low cost voltage regulator suitable for use with VFO's, frequency standards, and other equipment having small a.c. power requirements (approximately 20-30 watts) is shown in Fig. 1. This circuit is almost identical to the one suggested by Lamkin Laboratories for use with their MFM frequency meter. (Switch and fuse added.)

This circuit will reduce voltage variations to about one third; the output will be approximately 100 volts RMS. In addition to the improvement due to the regulated line voltage, the reduced results in less heat being produced in the oscillator. By using this circuit, the filaments are operated at a reduced, regulated voltage.

The regulator should not be placed near the oscillator circuit as it produces considerable heat. A separate chassis is suggested, and the switch in the load should be shorted as operating the regulator without a load can ruin the OC3's.

We have used this regulator with a MFM for almost a year with great success. The cost is low and the construction very simple; give it a try.

The Vanguard 501 TV Camera

Talking to people over the radio is certainly one of the most intriguing hobbies that exists—as all 73 readers certainly know. But think how much more fascinating not only talking, but seeing, your contacts must be. Most hams have had at least some thoughts about ham television, but most have also never thought seriously about getting on TV because in the past, TV has been complex and costly, and TV signals have limited range and there have been few hams on amateur TV.

Well, TV signals still don't travel very far, but modern techniques of high power, high gain antennas and low noise converters have made reasonable distances possible. And more and more people are getting on TV. Transistors, varactors and modern transmitting tubes have made TV less complex than it once was, and the cost isn't unreasonable. It certainly can cost far less to put a TV station on the air than many hams spend on commercial sideband equipment. Obviously, TV isn't for all hams, but the experimenter can have plenty of fun with it. In large cities, for instance, licensing classes can be telecast to prospective hams, or technical sessions held for those wishing to increase their knowledge (or license class). The receiving converters for regular TV sets can be quite simple; see the article by PAØVDZ in this issue, for example. ATV'ers have telecast church and other events of interest to bed-ridden persons or others. I'm not sure where the FCC draws the line on broadcasting on ham TV, but there are obviously many possibilities for public service and good publicity for hamming with TV. Think of the fame you'd receive if you were to start the first (and only) TV station in a small town!

You can get on TV with a flying spot scanner, an obsolete converted surplus camera, or even a cast-off commercial camera, but there's no question that the most practical type of signal source is a modern, inexpensive vidicon camera designed for closed circuit TV such as the Vanguard model 501 camera. I've had the chance to play with one for some time now, and though I haven't put it on the air

yet—at least on a ham band—I've come to the inescapeable conclusion that I should. Let's take a look at the Vanguard 501 and see what it has to offer:

In the first place, the 501 is tiny. Until you see it, it's hard to believe how small it is. It's almost the same size as five small pocket books in a pile. The small size is a result of the complete transistorization of the circuit (except for the vidicon and neon bulb HV regulators) and the compact, modern, plug-in etched circuit board construction. The camera weighs only 3½ lbs., yet seems to be very sturdy and well-made.

The 501 uses twenty transistors, including a low-noise VHF field effect transistor input amplifier. A clever part of the circuit is that the vidicon is used as a light sensor to set the camera for best conditions with lighting changes. The power supplies are regulated.

Output is either standard 1.5 volt video for use with a video monitor, modified TV set, or TV modulator for a transmitter, or rf for direct feed to the antenna terminals of a TV set tuned to a low band channel. The video output gives better quality, but the rf output is obviously more convenient. There's certainly plenty of output: I used the camera with 250 feet of coax with no problems (except that we did get into the neighbor's set on a blank channel. Good for remote baby sitting, I guess.) In either case, the quality was excellent. Everybody in the neighborhood, and all of their children, had to look at themselves on TV, and though all of them thought their likenesses horrible, they also agreed that everyone else looked very natural and that the camera did a magnificent job.

The camera worked well with only normal room illumination, or in the bright sunlight. Even with a small bulb at night, you could get a pretty good picture. The lens is inexpensive. It's 8 mm rather than the more expensive 16 mm variety, so telephoto and other extra lenses could be added to the 501 without spending a lot of money.

The only trouble I had with the camera was erratic noise in the picture at first. This was apparently due to a bad ground, and was easily cured by tightening a fairly-obvious loose mounting screw.

No schematic or instruction manual comes with the camera, though Vanguard has reported that one will be made available in the future. The camera is guaranteed for a year except for open filament or breakage of the vidicon.

As you can tell, I'm real pleased with the 501 I have been using. It is certainly an excellent buy at \$279.95. . . . WA1CCH

The Shackcom

A simple intercom that can be built from junk-box parts.

For all those who have felt the need of a communication link between the shack and the household I have a solution. The Shackcom shown in Fig. 1 is a inexpensive, simple, and compact, two-way intercom. The circuit employs the three distinct types of transistor amplifiers and thus would serve as an excellent introduction to transistor circuits: T1 is in the common base configuration and thus transforms the 8 ohm speaker impedance to high impedance. T2 is in the common collector configuration and thus transforms the high Z output of T1 to about 400 ohms with a power gain. T3 is in the common emitter configuration and thus raises the 400 ohm output of T2 to a slightly higher impedance with a large gain in power. T4 and T5 are also in the common emitter configuration and develop the power needed to drive the second speaker.

Nothing about the circuit is critical. The output transformer T as well as the transistors T4 and T5 were taken from a discarded transistor pocket radio. The electrolytics can be of any value in the microfarads. The speakers used should be of the 8 ohm type, ½ watt, and with at most 5 inch cones. The volume control R is not necessary since the maximum output of the Shackcom is not excessive as long as the person speaking is at an arm's length from the speaker cone. The 2N404s are sold for ten per \$1.00 by Poly Paks.

The prototype of the Shackcom was built on a 2" x 7" circuit board, and mounted in a 3" x 5" x 7" box with a 4" cone speaker. The circuit 1 is drawn in such a way to suggest how the Shackcom could be laid out on a printed circuit board.

. . . W8MQW

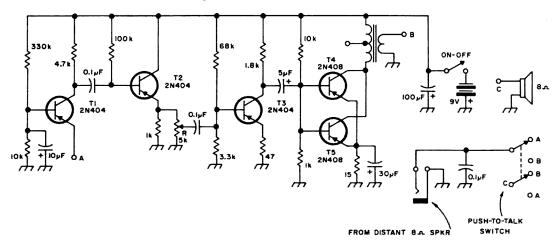

Fig. 1. The Shackcom—a simple transistorized intercom. Three types of amplifiers are used: common base (T1), common collector (T2) and common emitter (T3 and T4 and T5).

Butch Plugs

When you're working on a chassis or panel and make a butch by drilling or punching a hole in the wrong place, sometimes it can be a problem. For the larger size holes (about ¼ inch and above), you can buy a hole plug from one of several manufacturers. How about small drill holes? Very simple, mix up a batch

of epoxy adhesive and fill the hole up. Make sure there is a little additional material above the surface of the panel. When the epoxy hardens, it tends to shrink slightly, and if sufficient material is not left on the surface, a small indentation will result. After the epoxy hardens, sand it smooth. A little paint and nobody will ever know that you drilled a hole in the wrong place.

Gus: Part 19

After a very FB stay at Diego Garcia Island we all boarded the ship and took off for Salomon Island, another in the Chagos Archipelago. This island is some 50 to 75 miles away from Diego Garcia. We were met there by the manager of Salomon Island and invited to have supper at his house. He had his wife with him, a very charming person whose hobby is painting. She had a very large assortment of paintings of the islands, some of which would have won honors at any artists' showing. Believe it or not, they actually had a Coca Cola-they had had it for about ten years, I think. When it was opened it did not even go plop; it was completely flat. In South Carolina I would be afraid to give it to my dog for fear the dog would turn up his nose at it. But on Salomon Island that one Coke tasted like something direct from Heaven. We were served a very elegant meal, prepared undr the directions of the manager's French wife. Of course they had many different kinds of wine-what Frenchman does not? Late that night we went back to our ship. I did a little operating /MM for a few hours.

Early the next morning we loaded up the copra there and about noon we lifted anchor and were away for VO9, Mahé. This return trip was a real dream ride: all the way "down wind." Hour after hour I would lie back in a deck chair watching the flying fish. They would all take off like a covey of partridges and sail through the air for a hundred feet or so. These Indian Ocean flying fish actually get about 20 feet above the water and sail with the breeze just like a bird. It's a beautiful sight to behold; they are a bright silver and actually shine in the sunlight. At night I used to like to watch all the apparent fireworks down around the propeller if the engine was running, or just at the point where the water passed the rear sides of the boat if it was under sail. They tell me it's some kind of algae in the water. How this stuff can look like fire when it's submerged I don't quite understand, but there it was every night. Looking south at night I could just see the Southern Cross on the horizon, not almost overhead as on Bouvet Island way down South, and not almost overhead as the North Star is when in the Faroes. There was always a nice cool breeze on the ship's decks and this trip back was about the nicest one I have ever had on any boat anywhere. We were out of the monsoon belt on this trip and this made the trip a real smooth one.

Upon arriving back at Mahé and paying for my trip to the Chagos, away I went again to my little "Hotel de Seychelles" where it was costing me \$22.00 per week for room and board. When I was there they had no electricity at the hotel except their dc current which was no help to me at all. So it was connect up my little putt-putt again and buy some gasoline (they call it petrol) for something like 80¢ per gallon. The hotel there now has ac current from Port Victoria, I understand. That's the hotel that has thatched huts for each hotel room, all in a long row up and down the beach. They always gave me the one on the end so that my putt-putt would not keep everyone awake all night when I was on the air. Incidentally the food there is very FB: plenty of breadfruit, pineapples, oranges, coconuts, lemonade, fish cooked every way possible, turtle meat quite often, swell pastry, plenty of good home cooked cake, and even once or twice per week they have ice cream. All this for \$22.00 per week. Not bad, eh? I again headed down to the dock area every time I had the chance. I had shipped there 3 forty meter AM phone rigs with the right model ARC receivers to tune 40. They wanted one installed at the owner's home on Mahé. one at his son's home on Mahé and the other down on Aldabra Island. Aldabra has no radio link with the outside world at all; all they have is a transistor radio to listen to the BBC and get the news.

Another boat was soon taking off for Aldabra Island, going via Cosmoledo and Assumption Islands. They decided to have the unit installed on Assumption Island instead of Aldabra since they were planning on cultivating guano on Assumption shortly. They told me to be ready to leave in two days.

If you want to see a new way to install a 70-foot bamboo pole get these Seychelles fellows to do the job. Here is how they put one up for me: they dug a nice hole (with their knives) right below the point where there were two big limbs on a tree that looked like an oak. One fellow got up in the tree with a piece of rope. They then put the small end of the bamboo at the edge of this hole they had dug and tied the rope to the small end of the bamboo. Then the other ten fellows started pushing the large end of the bamboo towards the hole while the fellow up the tree pulled up the small end. The large end was eventually dropped into the hole. I tried explaining that there were better ways to do this job, but none of them spoke English. I learned that there are many ways to do a simple job, many of them different from the way we have always done it back in the States. It makes you want to pull out your hair (and I ain't got much to pull!).

This ship that was going to Aldabra was going mostly to haul back a load of those very large turtles. The stop at Assumption was to bring back its manager, and to also install the 40 meter AM rig there. This was a fairly good sized ship (about 3 times as large as Harvey's-VQ9HB). The captain was a 100% full blooded Seychelles captain, tough as nails, with a good loud voice that his crew could hear even in the middle of the monsoon. He was the boss on that ship; when he spoke, they jumped. To me he was as kind as a father, so I have no complaints. Down to the ship I went and loaded everything on board. putting my /MM rig right up in the poop deck beside the big wheel. I mounted my putt-putt this time way up on top of the crew's sleeping quarters roof, because the S.E. monsoon was at its peak now and we all knew we were heading right into its teeth. I wanted to keep the water from getting into my putt-putt. Even up there it did get soaked by some of those monstrous waves. Those waves were killers down around the Aldabra area, and Aldabra is partly shielded by northern Madagascar.

As I said, we left VQ9 and headed for VQ9C (Cosmoledo group) making a very short 2-day stop there to pick up some copra and dried fish and deliver the usual mail and some much needed supplies. Then we were on our way to Assumption Island, right down in what Harvey calls the Cyclone Belt. We did really get a full dose of winds, rain and I don't know how high the waves were, but to me they looked like mountains falling down on the ship. We were tossed every which way and it was a battle staying in our bunks even

with their side-boards up. Sea sick-don't make me laugh. Those fellows on that ship did not know what that word even meant. As for me—I had a long time ago found how to control those butterflies in my stomach. Just tell yourself that you are not going to get sea sick, make yourself believe it and you have it made. So there was no sea sickness even with the tossing ship all the way, every minute of every day. It never did come up for a breather as it does sometimes during the year. I had installed my rig up in the poop deck and we were up about 40 feet, where every roll and rock of the boat was multiplied by about 5. To sit fastened down at my operating position I soon learned to get in swing with the ship. I became a part of the boat; when it rocked, I rocked along with it. I told someone over the air I had the Aldabra Swing while I was on /MM, and I really meant it. This was exactly the opposite of the return trip from the Chagoes with that nice steady breeze blowing up back of us, pushing us along at a very steady rate.

After about 6 days we sighted Assumption Island. We anchored off shore about one-half mile down wind from the island. The island shielded us pretty well from the high seas. I loaded up everything and went ashore in the first landing boat. While they unloaded some lumber, doors, windows, etc. to build some small houses, I did some operating. I also mounted the wind-driven battery charger and two large 12-volt batteries, the ARC-5 being 24 volt operated. I got the wind-charger in operation and explained to the island manager that they should charge one battery one day and the next one the next day (the wind charger was only for 12 volts). He said he understood me (which I still have my doubts about). The modulation of this AM phone rig was way down and I was not satisfied with it at all but we had to leave the island the next day. A hint to anyone taking equipment to out-of-the-way places: test and test your equipment over and over and make sure that it's really on the ball before you ever leave the USA. You cannot ever be too careful, because out on some remote island there is no radio supply house around the corner. You cannot even find one bolt or nut on these islands. You bring along everything you need, or you do without and patch up the best you can.

We departed from Assumption Island for Aldabra Island, the distance between them being something like 50 miles. Incidentally, any of you who worked me while 1 was on Assumption Island don't have a new one; it counts the same as Aldabra since it's actually

in the same group. The high seas were still pounding away when we left and the going was pretty rough until we anchored sort of behind and in the shadow of Aldabra. Ashore we all went, the usual mail was delivered, up went my antennas again and I was on from Aldabra for the second time. The pile up was not as big as before but it was still there. To me it was always interesting to tune across a band that's very quiet and practically no one is on. You think everyone is off the air and that you have wasted your time going to that spot. Then you call that first CO; back comes mavbe one station. You exchange reports with him and stand by. Then maybe 2 or 3 stations call and you come back to one of them. On about the third QSO there are maybe 25 stations calling you. From then on the pile-up pyramids. It's up to you to work that pile down faster than they pileup! You keep saying dwn 5 or up 5 every now and then; even doing this the "lids" still keep calling you on your frequency. I have heard a number of stations that insisted on calling on my frequency, hour after hour, and day after day. They never get a QSO because it has always been my policy to never work anyone on my frequency. You newcomers to this game of DXing, take a hint from someone who has been in on the pile up from both ends. Listen to what the DX station tells you to do and do it. Try and find a station he works, listen to this station's speed and style of operation and try your best to imitate this fellow. Observe the frequency of the fellows he is working, try to figure out how the DX station is tuning, try to outguess the other fellows in the pile. Maybe do what Frank, W5VA, does; watch for that peak signal condition and "nail the DX station" at that moment. That's the way to get that S-9. . . .

. . . Gus

Storing Test Leads

If your workshop is like most, your clip leads and test prods are always scattered all over the bench; and when you do pick them up, there is no convenient place to store them. A neat solution to this storage problem is to install two screw eyes in the wall about 30 inches apart; a piece of soft iron mechanics' wire is then strung horizontally between them and connected securely at the ends. To store leads with alligator clips, simply clip one end of the test lead to the storage wire and let the other end hang free. To store leads without alligator clips, just loop them over the wire. With this method of storage your test leads are always where you can find them.

HERE IT IS!

THE EXCITING XT-1A TV CAMERA KIT

26 SEMICONDUCTOR CIRCUIT (17 pmp transistors, 8 silican diodes and 1 zener) 6 STAGE HIGH GAIN, LOW NOISE VIDEO AMPLIFIER ● SELF-CONTAINED ELECTRONIC REGULATED POWER SUPPLY ● 1 PIECE PRINTED CIRCUIT BOARD CONSTRUCTION ● RF (ch. 2-5) or VIDEO OUTPUT

KIT CONTAINS: Anodized aluminum cabinet, printed circuit board, lens, lens mount, focus and deflection coils, power transformer, transistors, resistors, capacitors, small coils, switches, pots, knobs, vidican tube sacket, coax output connector, diades, hardware, wire PLUS OUR LARGE, EASY-TO-FOLLOW CONSTRUCTION PLANS.

In addition to this camera we have a complete line of tube model STARTER and MAJOR COMPONENTS KITS starting as low as \$18,95! For detailed into an all our hits PLUS block diagrams and off-intercorphotos send 10c for our information packed 1966 catalog. DON'T BUY UNTIL YOU'VE COMPARED our UNBELIEVABLE PRICES with our competitors! Low cost x Quality—an ATV RESEARCH MI.

Post Office Box 396-5 ATV RESEARCH So. Sioux City, Nebr. 68776

TICKLE YOUR TIGER!

Now that you have overcome your ignition noise, install a

DELTA MARK TEN CAPACITIVE DISCHARGE IGNITION SYSTEM

Enjoy dramatically improved acceleration — eliminate plug fouling and the effects of point bounce. Get better gas mileage and instant starts.

Installs in ten minutes utilizing original coil. Utterly reliable and fully warranted. Not to be confused with earlier "transistor ignition systems."

A Little About Noise

Perhaps more than a little; Bob's treatment of this important, but little understood subject is careful and complete.

Noise. This word describes the natural phenomenon which establishes the limiting range of all communication systems. To the DX man noise is the reason he can't work ZS1 at noon on 80 meters. Sure, a little of his signal reaches ZS land, but it is so far under the noise that it is useless and undetectable. To the VHF man noise is what stops him from working KL7 on 432 MHz. Again, some signal might get to Alaska by various means, but its very weakness, compared to the noise level at the receiving location, defies reception. Noise even affects the 75 meter ragchewer when a nearby electric shaver or ignition system tears up the signal he's listening to.

Now since noise has so much to do with establishing the limits of our ability to communicate, it seems wise to reach an understanding of what noise is, and how we might cope with it. And that brings us to the purpose of this article. If you stick with us from start to finish you will emerge with some basic knowledge of noise in radio systems. You will have an understanding of what noise is, what

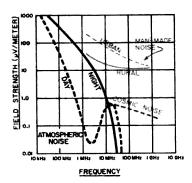

Fig. 1. Showing how the intensity of various types of noise sources varies with frequency. Source of graph: Reference 5.

causes it, and how to eliminate a good part of it from your receiving system. Further, such vague subjects as "equivalent noise temperature," "noise figure," and "minimum discernible signal strength" will be explained. But enough of this introduction, let's get into the meat of the subject.

What is noise?

Before discussing any technical subject it is always a good idea to define the terms to be used; then it is clear just what is being talked about. So, just what is noise, how can we define it?

In the most general sense, noise is any signal at the output of your receiver other than the one you want to hear. Therefore, noise is the hum and hiss, the static crashes, the ignition pulses, and the kilowatt tuning up 200 hertz from the signal you're tuning. The latter is more properly termed an "interfering signal", though, and we won't class it as noise. This article will treat all the others, as noise. Let's look at some specific noise types.

Cosmic noise. This is noise radiation that originates outside our atmosphere. It may come from the sun, our own galaxy (the Milky Way), from other galaxies or from some discrete "radio stars" which have been discovered. A great deal of it does indeed originate at the sun. The level of this "solar radiation" or "solar noise" varies from low "quiet sun" levels to magnitudes which are as much as 50 dB greater during "disturbed sun" periods. Sometimes solar radiation is even responsible for periods of radio blackout.

Most people have seen the band of stars in the sky known as the "Milky Way". These

Fig. 2. Noise equivalent circuit for an electrical conductor or resistor.

are mainly the stars of the galaxy of which our own sun and planet are members. Our galaxy takes the general shape of a saucer and since we are on the saucer, the rest of the galaxy appears as a band of stars when we look in the right direction. If we point a high gain VHF antenna at this band we will observe that the receiver output noise level increases. In particular, if we point it at the center of the galaxy, where the concentration of stars is greatest, we will note a 10 to 20 dB noise increase over other directions on the "galactic plane". All these stars are generating noise in a manner similar to our own sun, which is itself a star. There are some particularly noisy stars which have been recently discovered and these are among the ones called radio stars".

Altogether cosmic noise is believed due to the "black body" or thermal noise (explained below) radiation of the interstellar bodies. It is not particularly strong except in the region 10 to 300 megahertz where it is sometimes the chief contributor of noise to the radio system, and thereby establishes the smallest signal that can be detected. The intensity of cosmic noise decreases as the frequency is raised.

It should be mentioned that cosmic noise does have one good side—it is providing the signals which radio astronomers are studying to help us learn more about the nature of our universe.

Atmospheric noise. As hard to believe as it may seem to be, there is an average of about 2000 thunderstorms going on all the time at various points on the earth. Each of the thunderstorms produces lightning discharges, and there is an average of about 100 of these occurring every second. A lightning stroke is very similar to an electric arc, or spark, and generates a considerable amount of radio noise over a wide frequency range. This is the chief generation mechanism for atmospheric noise.

Now the generated noise is propagated for long distances, particularly in our DX bands, just as are the signals from our transmitters. Consequently, noise that originally came from a lightning stroke over Moscow may interfere with your QSO with a VK2 on 20 meters. In fact the intensity of atmospheric noise is dependent on time of day, season of the year, frequency of operation, weather and geograph-

ical location of the receiver. As a general rule, atmospheric noise decreases with increasing frequency, although there is an exception to this rule, as seen in Fig. 1. Also, the intensity decreases with increasing latitude of the receiving location. The thunderstorm seasons of equatorial Africa, the Caribbean, northern India, and other areas along the equator, make these locations particularly noisy.

Another source of atmospheric noise is "black body" radiation by the atmosphere itself. This is usually not particularly important today, but within a few years as more amateurs use the UHF bands we will have to learn to combat its effects, since it increases at frequencies above 1000 MHz.

Fig. 1 shows that atmospheric noise ceases to be a prime noise source above 50 MHz. This is due to the loss of long-distance signal propagation at the higher frequencies. Below 30 MHz, however, we do have to concern ourselves with limiting the effects of this noise as much as possible. Some means of achieving this are the use of high transmitter power, receiver bandwidth no wider than the signal received, peak-limiting or noise-silencing devices for high amplitude, short duration pulses from nearby lightning flashes, and the use of high gain receiving and transmitting antennas. And of course these means are generally useful for combating the effects of other types of noise as well.

Man-made noise. In the frequency range from 1 to 500 MHz there is considerable noise radiated by the machines man creates to do his work for him. A classic example of this type of noise is the impulsive signal emanated by the ignition system of an automobile. As with lightning, the generation mechanism is an arc, this time at the spark plugs. Anyone who has had an unsuppressed automobile pull up next to his receiving antenna knows what this type of noise can do to even a strong signal. Noise-blanking devices are usually about the most effective in eliminating this type of noise. Also, since man-made noise is generally vertically polarized, maximum utilization of horizontal antennas should be employed in areas highly populated by automobiles and other noise-generating machinery.

Other sources of man-made noise are power-line leakage, electric motors, and industrial heating generators. Noise from these devices can be so severe as to interrupt even commercial communication and broadcasting. At least one space shot from Cape Kennedy is believed to have aborted due to an interfering signal from some man-made source. Since man-made noise is mainly due to ma-

chines, it is usually higher in intensity in the city than out in the country. See Fig. 1.

Thermal noise

We now come to the single most important source of noise. Thermal noise is important not only because it is present in radio systems, but also because it is useful in theoretical developments to represent other types of noise by an equivalent amount of thermal noise. Consequently, a good understanding of thermal noise is absolutely essential to anyone who wishes to understand noise theory as applied to radio.

Just as total darkness is the absence of all light, so absolute zero is the temperature when all heat is absent. There is a temperature scale with absolute zero as its zero point. This is the Kelvin system. Zero degrees Kelvin is absolute zero, 273 degrees Kelvin is the freezing point of water and 373 degrees Kelvin its boiling point. Kelvin system temperature can be found from Centigrade (Celsius) system temperature by:

(1) Degrees Kelvin = Degrees Centigrade + 273

Now let's look at a conductor of electricity. Since there is no perfect conductor, it will have some resistance, and therefore we can treat it as though it were a resistor. Now if the resistor is sitting in a room, its temperature is probably about 290 degrees K. Under this condition the electrons in the resistor will be moving about in a random fashion. This random motion of the electrons creates a random voltage across the terminals of the resistor. By random we mean that we cannot predict what the voltage will be at a certain time in the future. However, we can state what the mean voltage will be, thanks to a man named Nyquist. The formula that he developed is this:

$$v_{n} = \sqrt{4kTBR}$$

 v_n = Mean noise voltage, volts

R = resistance, ohms

k = Boltzman's constant,

= 1.37×10^{-23} joules/degree K

T = Temperature, degrees K

B = Bandwidth, cps

Here the word "mean" is similar to "average", but a strict definition can be found in the textbooks referenced. Notice that the mean voltage is dependent on the bandwidth across which it is measured. This implies that the noise is evenly distributed across all frequencies, and this is truly the case, at least in theory. Noise that is distributed in this fashion is termed "white noise". We can now draw

the noise equivalent circuit for an electrical conductor, or resistor. See Fig. 2.

The next question that we might ask is, what is the noise voltage if I have two or more resistors in series or parallel? It can be shown mathematically that Fig. 2. can still used. First you find the effective resistance of the combination, this is then R. Then v_n is found from this R, by using Equation (2). Consequently, it is pretty simple to find the noise equivalent circuit for most resistive networks.

There is one more thing to be looked into about this noise voltage. Since its magnitude is random with respect to time, we cannot add two such voltages together directly (when they are in series) as we can with ordinary voltages. Voltage sources that cannot be added directly are termed "incoherent", and must be added by this formula:

(3)
$$v_{nT} = \sqrt{v_{n1}^2 + v_{n2}^2}$$

 $\begin{array}{l} v_{nT} = \ total \ effective \ mean \ noise \ voltage. \\ v_{n1}, \ v_{n2} = \ individual \ mean \ noise \ voltages \\ to \ be \ added. \end{array}$

This equation is illustrated in Fig. 3. Note that we will get the same v_{nT} whether we first combine the R_1 and R_2 and find v_{nT} directly from Equation (2), as in the last paragraph, or if we go to the trouble of using Equation (3). We are merely taking either of two routes to get the same result. However, both methods should be understood. Also, Equation (3) is not limited to the addition of just two incoherent sources. It can be extended to include as many voltages as must be combined. Thus for 5 incoherent sources:

(4)
$$v_{nT} = \sqrt{v_{n1}^2 + v_{n2}^2 + v_{n3}^2 + v_{n4} + v_{n5}^2}$$

where the notation is the same as in Equation (3).

Now we must find how much noise power is available from the circuit of Fig. 2. Most amateurs will tell you that you will draw the most power from a circuit like Fig. 2. when you load it with another resistance equal to R, and this is true. The new circuit is Fig. 4.

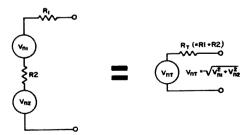

Fig. 3. Combining two resistors into their total equivalent noise circuit.

Fig. 4. Loading the circuit of Fig. 2 to obtain maximum available output noise power.

The voltage across R_L is $\frac{1}{2}v_n$, thus the power dissipated in R_L is (from Ohm's law):

(5)
$$P = \frac{E^2}{R} = (\frac{1}{2}v_n)^2/R_L = \frac{v_n^2}{4R_L}.$$

But since $R_L = R$:

$$P = \frac{v_n^2}{4R},$$

and from Equation (2) $v_n^2 = 4kTBR$. Thus,

(7)
$$P = \frac{4kTBR}{4R} = kTB.$$

Thus the maximum available output noise power is kTB. Note that it doesn't depend on what value R has. Therefore any conductor or resistor has the same available noise power at its terminals. This is a very significant fact and helps to simplify noise theory, as we shall see.

As noted above thermal noise is often used to represent other types of noise. This is because thermal noise is easily represented and worked with mathematically, while other types of noise often are not. Consequently, if we have a certain amount of noise power available from some source we can, by using Equation (7), represent that source by a resistor at the temperature T which gives the same available noise power output. (The bandwidth, B, over which we measure the available noise power must be the same for the source and our representation, of course.) Thus any noise source has an equivalent thermal noise temperature, or just "noise temperature". This is a very important fact to understand. For example, as noted above, the noise temperature of a star is roughly its actual temperature, because its output is mainly thermal noise.

We can now leave thermal noise for awhile and turn to another subject. If you feel a little hazy on some of the points covered above, refer to one or more of the references listed in the bibliography for extra instruction, or to get another viewpoint.

Noise in receivers

Up to this point we have mainly concerned ourselves with noise generated outside the receiver-antenna system. The only exception to this has been thermal noise, which is generated both within and without the receiving system. We now must concern ourselves with noise generated within the receiver itself.

Noise is generated in a receiver in several different ways. There is thermal noise due to the resistive elements in the receiver circuitry, and there is noise somewhat like thermal noise that is caused by the vacuum tubes and semiconductors in the receiver. These foregoing types of noise can be minimized by designing the receiver for low noise figure. Unfortunately, there are three other noise generation mechanisms within the receiver that cannot be minimized by design for low noise figure.

Cross-modulation. There are two ways in which two or more signals can mix together within a receiver to produce a third signal, which interferes with the desired signal. One of these ways is through cross-modulation. Cross-modulation requires the presence of only the desired carrier and another undesired carrier which is modulated. In cross-modulation the modulation on the undesired carrier appears on the desired carrier, that is, the modulation "crosses" over from the undesired to the desired carrier. The effect is due to limited dynamic range in the receiver. The undesired carrier does not necessarily have to be within the if passband of the receiver, and more often is not. The cross-modulation effect usually takes place in the stages of the receiver close to the antenna. The stronger the undesired signal, the more likely the effect is to be noticed. Low cross-modulation requires special design effort and designing a receiver for lowest possible noise figure will usually cross-modulation characteristic make the

Intermodulation distortion. This is the other way in which signals may mix in a receiver to produce a third, interfering, signal. Again it is due to limited linear dynamic range in the receiver. Intermodulation does not require the presence of the desired signal. It is the mixing of two undesired signals, or their harmonics (which are themselves generated within the receiver), to produce a third signal at or near the desired signal frequency. Again, this type of noise generation requires special design effort for its minimization, and a low noise

Fig. 5. Representation of an amplifier circuit. G_{τ} is voltage gain, v_{\circ}/v_{s} . G_{a} is available power gain.

figure design scheme will make it worse.

Noise modulation. This effect is merely a combination of cross-modulation and intermodulation distortion. Once again it is due to receiver non-linearity. Since noise is always present in the receiver, there is always a source of "signals" to produce the cross- and intermodulation effects. As a consequence there is always modulation of the desired and undersired signals by the noise in the receiver. If it were not for noise modulation, you would not notice any difference in output when tuning across an unmodulated carrier with an AM receiver. This is because the detector only responds to the modulation on the carrier, not the carrier itself. But since the noise modulation effect modulates the carrier with noise, you get the characteristic hissy noise output. Reduction of cross- and intermodulation effects will reduce noise modulation also.

Now we have an idea of some receiver noise problems. We will discuss them some more, but now it is time to turn to another topic.

What is power gain?

If you ask a typical amateur what the power gain of an amplifier is, he will probably tell you it is the output power divided by the input power. In a sense he is right, but there is a bit more to it than that. An understanding of that "bit more" is necessary to those who would understand noise theory.

Have a look at Fig. 5. (We will consider all impedances to be purely resistive.) Here we have a source of input power, made up of $V_{\rm s}$ and $R_{\rm s}$, which we will amplify with the amplifier in the box. The amplifier has an input impedance $R_{\rm p}$, and an output impedance $R_{\rm p}$. The load is $R_{\rm l}$. Now we can define several different power gains. The first we shall call just plain "power gain". It is defined thusly

(8) power gain = G_p

 $= \frac{\text{power going into } R_1}{\text{power going into amplifier from source}}$

Of course "power going into R_i" is the same as amplifier output power.

Now the real purpose of a power amplifier is to increase the power available from a source. But "power gain", as defined above, doesn't tell you whether the amplifier is actually achieving this or not. For example, if R_s and R_j are widely different very little power will get into the amplifier to be amplified and even with a large power gain the output power that is available from the amplifier may be very small, maybe even less than the source

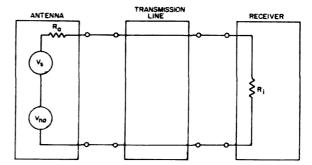

Fig. 6. The receiving system.

had available to begin with without the amplifier. In this case the amplifier would be doing more harm than good, for it is adding noise to the system, without increasing the available signal power. Consequently a better measure of amplifier gain is needed. This is called "available power gain":

(9) available power gain = Ga

 $= \frac{\text{power available at output of amplifier}}{\text{power available from source}}.$

The power available from the source is (remember how we got Equation (7)?): $v_s^4/4R_s$. And the power available at the output of the amplifier is: $v_o^2/4R_o$. Therefore:

(10)
$$G_a = \frac{V_o^2/4R_o}{V_s^2/4R_s} = G_v^2 \frac{R_s}{R_o}.$$

 G_a will be maximized when the input is matched, that is $R_j = R_s$, but is unaffected by the match between R_o and R_j .

We shall make considerable use of this available power gain in the development of noise figure theory. But while we're about it we may as well define two other types of power gain, which you will see more and more frequently nowadays and may not otherwise understand. The first of these is "transducer power gain". It is defined thusly:

(11) transducer power gain = G_t

 $= \frac{\text{power going into } R_l}{\text{power available from source}}$

Maximizing G_t requires matching both R_j to R_s , and R_l to R_o . A little thought will show that G_t is always less than or equal to G_a . In other words, G_t for a particular amplifier will never exceed its G_a .

The other frequently used gain figure is "insertion power gain". It presupposes that source and load impedances have been specified, and is a measure of the effectiveness of "inserting" a particular amplifier between the given source and load.

(12) insertion power gain

 $= \frac{\text{load power with amplifier}}{\text{load power without amplifier}}.$

The receiver-antenna system

We now have enough preparation behind us to begin a discussion of the receiving system. This system is composed of the antenna, the receiver, and the transmission line connecting the two. Fig. 6 is a representation of the system.

The transmission line will have a certain amount of loss, of course. We can look at this another way, though. Since part of the signal is lost due to the attenuation of the transmission line, there is less signal power available at its output than at its input. Therefore, the line has an available power gain of less than one. It turns out that the available power gain of the transmission line is equal to the inverse of its loss:

(13)
$$G_{aTL} = \frac{1}{L_{TL}}.$$

(Subscript TL means transmission line)

For example, if the loss is 2 (that is, 3 dB), the available power gain is ½ (or -3 dB).

Note that the antenna is represented by a resistance (we are assuming the antenna to be lossless and resonant) and 2 voltage sources connected in series. Let's look at each of these components one by one.

R_a is merely the radiation resistance of the antenna. This is the resistance that would be measured by an ohmmeter looking into the antenna terminals. Don't try it with your VOM, though, because the ohmmeter must operate at the resonant frequency of the antenna.

v_s represents the signal voltage. The antenna is immersed in an electromagnetic field generated by the transmitter we want to listen to, and the result has been the conversion of the field strength into the voltage, v_s.

 v_{na} represents the noise voltage. Part of this noise voltage is due to the thermal noise generated in R_a . The rest of the noise voltage is due to atmospheric, cosmic, man-made and other types of noise. This we term "excess noise", because it is excess to the inherent thermal noise in the antenna.

The antenna's actual temperature we shall call T_{ao} . Therefore the thermal part of the noise voltage is

$$\sqrt{4kT_{no}BR_{n}}$$
.

But remember we said awhile back we can

represent any noise by an equivalent amount of thermal noise, merely by raising the temperature of the representative resistor to the proper value. This is what we are going to do in the antenna. The total effective antenna noise temperature we shall call T_{aeff}. Therefore:

(14)
$$v_{ns} = \sqrt{4kT_{a,eff}BR_a}.$$

 $T_{a,eff}$ is the sum of the actual antenna temperature, T_{ao} , and an excess temperature, $T_{a,ex}$, which represents all the noise except thermal noise:

$$T_{a,eff} = T_{ao} + T_{a,ex}.$$

If there were no noise except thermal noise in R_a , then $T_{aveff} = T_{ao}$, of course.

in R_a , then $T_{a \cdot eff} \equiv T_{ao}$, of course. Fig. 7. shows how the excess noise varies with respect to frequency. Note that above about 700 MHz the excess noise has about disappeared, so that $T_{a \cdot eff} \equiv T_{ao}$, or in other words, $(T_{a \cdot eff}/T_{ao}) \equiv 1$. But below 700 MHz the excess noise gets larger and by the time we reach the 10 meter band (28 MHz) the excess noise is at least 100 times greater than the thermal noise. This great variation of the excess noise makes it necessary for us to divide our approach into two different parts. First we shall neglect the excess noise and look at the receiving system without it. Then we will put it back in to the system and see what changes we have to make to our thinking.

Noise figure

From Fig. 6 we can see that the antenna output contains noise as well as signal. With a given antenna there is little that can be done about this antenna noise, we just have to live with it. It would be nice though, if we could avoid having any additional noise added into the receiving system by the receiver. Unfortunately this is impossible, and the receiver does add some more noise. The receiver's noise figure is a measure of the additional noise contributed by the receiver.

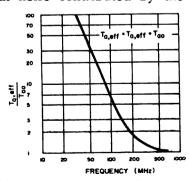

Fig. 7. Showing how $T_{a, eff}$ typically varies with respect to T_{ae} .

(This neglects any cross- or intermodulation effects in the receiver.)

The noise figure of a well designed receiver will be determined primarily by the "front end", that is, the stage or two closest to the antenna. Noise figure for an amplifier is defined thusly:

(16) noise figure =
$$NF = \frac{S_i/N_i}{S_o/N_o}$$
.

where: S_i = available signal input power S_o = available signal output power N_i = available noise input power N_o = available noise output power

This is merely the ratio of the input signal-to-noise ratio to the output signal-to-noise ratio. A perfect receiver would have a NF of 1 (or O dB).

Now we have the definition out of the way, let's see what we can do with it to find the receiver noise figure. First, if the transmission line is matched to the antenna and receiver input then the resistance seen by the receiver looking at the antenna is R_a. In this case S_i is the available power from the antenna multiplied by the available power gain of the transmission line:

$$S_i = \frac{v_{s}^2}{4R_a} \ G_{TL}.$$

The amplifier (receiver) available output is S_i multiplied by the available power gain of the amplifier (receiver): $S_o = S_i G_{aR}$. (G_{aR} is the amplifier, or receiver, available power gain.) The available input noise power is (neglecting antenna excess noise for now): $N_i = kT_{ao}B$. And the available output noise power is: $kT_{ao}BG_{aR} + \Delta N$. ΔN is the available output noise generated within the amplifier (receiver).

Now if we put all these quantities into Equation (16) we come up with:

(17) NF =
$$\frac{kT_{ao}BG_{aR} + \Delta N}{kT_{ao}BG_{aR}} = 1 + \frac{\Delta N}{kT_{ao}BG_{aR}}.$$

Notice that we would only have a noise figure of 1 if $\triangle N$ were O, which require a perfectly noise-free receiver.

Now take another look at Equation (17). Note that the receiver noise figure is dependent on the source temperature, T_{ao} . In order to avoid confusion, the radio and communications industry has decided that noise figure will be measured at $T_{ao}=290$ degrees K. If it were not for this standardization noise figures published by one manufacturer would be difficult to compare with those published

by another. Remember, noise figure depends on source temperature.

Receiver noise temperature

Often nowadays you will see the noise performance of a receiver (particularly the very low noise variety in the VHF and UHF range) specified in "receiver noise temperature." You may have asked yourself, what does this mean? How can I relate this noise temperature to noise figure which I understand better? Well, let's see.

Once again remember that noise is often represented by an equivalent amount of thermal noise. What we are doing with our receiver is pretending that the additional noise, ΔN , comes from a source at the receiver input terminals. This source must be at a temperature, $T_{R,eff}$, to account in a thermal way for the additional receiver noise. Therefore, $\Delta N = kT_{R,eff}BG_{aR}$. Now putting this into Equation (17):

$$(18) \quad \mathrm{NF} = 1 + \frac{\mathrm{k} \mathrm{T}_{\mathrm{R,eff}} \mathrm{B} \mathrm{G}_{\mathrm{aR}}}{\mathrm{k} \mathrm{T}_{\mathrm{ao}} \mathrm{B} \mathrm{G}_{\mathrm{aR}}} = 1 + \frac{\mathrm{T}_{\mathrm{R,eff}}}{\mathrm{T}_{\mathrm{ao}}} \cdot$$

Or,

(19)
$$T_{R,eff} = T_{ao} (NF - 1),$$

where: $T_{R,eff}$ = effective receiver noise temperature.

Note that $T_{R,eff}$ is a bit more arbitrary measure of receiver noise performance than NF, because it requires no reference temperature. Also, if you want to convert from NF to $T_{R,eff}$ (or reverse) be sure you measure the NF at the same T_{ao} as you use on the right-hand side of Equation (19). So now we can convert back and forth from NF to $T_{R,eff}$. By now you should have a fair understanding of what noise figure and temperature are.

Cascaded stages

Sometimes it becomes of interest to find the total noise figure for two or more stages in cascade. An example of this problem would occur if you had a new preamp in mind for your VHF receiver and wondered if it would really improve performance appreciably. We won't go into the derivation of the formula, but here it is for two stages:

(20)
$$NF_{T} = NF_{1} + \frac{NF_{2} - 1}{G_{a1}}$$

$$NF_{T} = \text{total effective NF}$$

 NF_T = total effective NF NF_1 = NF of first stage NF_2 = NF of second stage G_{a1} = G_a of first stage If you have more than two stages, the formula can be extended thusly:

(21)
$$NF_{T} = NF_{1} + \frac{NF_{2} - 1}{G_{a1}} + \frac{NF_{3} - 1}{G_{a1}G_{a2}} + \frac{NF_{4} - 1}{G_{a1}G_{a2}G_{a3}} + \dots$$

[notation same as for Equation (20)].

If it is necessary to find the total noise temperature for two stages:

(22)
$$T_{T} = T_{1} + \frac{T_{2}}{G_{a1}}$$

 $T_T = \text{total noise temperature}$

 T_1 = noise temp for first stage T_2 = noise temp for second stage

And for more than two stages, the formula is simply extended:

(23)
$$T_T = T_1 + \frac{T_2}{G_{a1}} + \frac{T_3}{G_{a1}G_{a2}} + \frac{T_4}{G_{a1}G_{a2}G_{a3}} + \dots$$

Excess noise again

In the development of Equation (17) we decided to assume the effective source (antenna) noise temperature to be T_{ao}, the actual temperature (which we further assumed to be 290 degrees K). But we know in the general case, below 700 megacycles, this is not the case, for the actual antenna noise temperature is Taleff. This would suggest that we should measure the receiver noise figure with a reference temperature equal to Ta,eff. We can see from Equation (17) that if we did this the noise figure calculated in this manner would get smaller and smaller as we decreased frequency, because Ta,eff gets larger and larger. This seems to imply that receiver noise figure becomes less significant at low frequencies.

Let's look at this another way. From Equation (18), we can define an antenna noise figure:

(24)
$$ANF = 1 + \frac{T_{a,eff}}{T_{ao}}.$$

100

ANF = antenna noise figure

But since Ta,eff increases as frequency decreases, the antenna noise figure would also increase. This would seem to imply that at low frequencies, the antenna noise figure would be so much larger than receiver noise figure, that the latter would become insignificant in the system.

What we have been hinting at in the two preceding paragraphs is that below some certain frequency, receiver noise figure is no longer an important design consideration. This is an important fact to understand. Due to the variation of T_{a,eff}, it has been determined that (using modern tubes or transistors in the front end) noise figure should not be considered in the design of a receiver for operation below about 100 MHz. This 100 MHz figure is purely arbitrary, and some present day authorities might tell you 200 MHz is a better figure.

What then are design considerations for a low-noise receiver below 100 MHz? The answer to this is primarily the cross-modula-

tion characteristic.

Our crowded DX bands today demand as little interference between signals as possible. One thing we can do to establish this condition is design our receivers for low cross- and intermodulation, so that the signals cannot mix together in the receiver and thereby create even more interfering signals. It is an unfortunate fact that a receiver cannot be designed for optimum noise figure and optimum cross- and intermodulation simultaneously. In fact the two types of considerations are in direct conflict. Consequently, we must decide between the two lines of design. Below 100 MHz we would decide in favor of low cross-modulation. Above 100 MHz we must begin to think in favor of low noise figure.

Minimum discernible signal

Our last topic will concern the minimum signal that can be detected by a receiving system. The development will be useful in that the final result will be an equation, examination of which will show how the weak signal performance of a receiving system can be improved.

Minimum discernible signal strength is defined here as the power density (at the receiving antenna) in the field of the desired signal which produces a receiver output signal power equal to receiver output noise power. We assume the antenna thermal noise is the dominant noise input component.

The input signal power under minimum discernible signal (MDS) conditions is:

(25)
$$S_i = A \times MDS |_{S_o = N_o}$$

 S_i = receiver input power A = antenna capture area MDS = as defined above

WE'RE IN PRODUCTION

OF OUR OWN TEST METERS **DESIGNED** BY EVANS ENGINEERS TO GIVE YOU

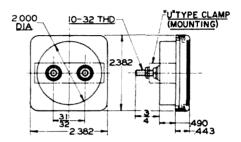

± 5% READINGS

Completely tested and in the field, this meter is a compact beauty, $2^{1}/_{2}$ inches square, and consists of a clear plastic front, metal back, well damped movement, quality metal dial, solid brass movement support for extra rugged construction, and yields on accuracy of $\pm\,5\%$ of full scale value. Mounts with U-clamp.

(The vertical bar with $S_o = N_o$ means the equation applies when output noise power is equal to output signal power.) Now rearranging Equation (25):

(26)
$$MDS = \frac{S_i}{A} \bigg|_{S_o = N_o}$$

But $S_o = G_a S_i$; and $N_o = G_a k T_{ao} B + \triangle N$, as above when we developed Equation (17). Therefore:

(27)
$$MDS = \frac{S_o}{AG_a}$$
, and since $S_o = N_o$:

(28)
$$MDS = \frac{kT_{ao}B + \Delta N/G_a}{A}$$

Now substituting Equation (17) into Equation (28):

(29)
$$MDS = (kT_{ao}B/A) NF.$$

Equation (29) is the end result we wanted. It shows that the MDS of a receiving system increases as the bandwidth and noise figure of the receiver increase, and decreases as the antenna capture area increases. The derivation of Equation (29) did not consider transmission line losses, but it is obvious that to

keep the MDS down we must use transmission lines with small losses. Also, it should be noted decreasing bandwidth will decrease MDS, but we can only do this until receiver bandwidth is about equal to signal bandwidth, for further reduction would make it impossible to recover the intelligence in the signal.

Conclusion

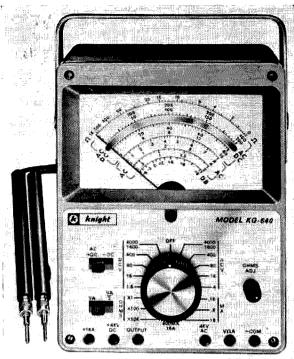

The intent of this article has been to provide a general overview of the receiving noise problem. It was particularly desired to point out when noise figure is and is not important in receiver design, and to show the relationship between noise figure, noise temperature, and minimum discernible signal strength. The author hopes that the reader has found it helpful to his understanding of noise.

The Knight-kit KG-640 VOM

If you're in the market for a volt-ohm-milliameter, the new Knight-Kit KG-640 seems to be an excellent choice. This 20,000 ohms per volt instrument has many plus features that vou don't usually find in inexpensive test meters. First of all, the meter is a taut-band unit: that is, the needle is suspended on a thin taut metal band instead of conventional bearings. Bearings, no matter how well designed, introduce a certain amount of friction. On the other hand, with the taut band movement, the friction is nil. This assures repeatability of reading plus dependable reliability. In addition, a mirrored scale on the meter face eliminates any errors that might be caused by parallax.

The KG-640 has a total of 57 different measuring ranges; many more than almost any other VOM on the market. On the DC scale, for example, the readings go from 0.8 VDC full scale (very handy for transistor work) up to 4000 volts. This range is sufficient for almost any DC voltage measurements that a ham is ever likely to make. The other ranges of AC voltage, resistance, current and dB are equally extensive. A complete list is given in the specifications below.

Although this VOM is available completely assembled, there are considerable savings if it is purchased as a kit. It is relatively easy to assemble with the very complete and easy to follow directions which are furnished. Plenty of illustrations are used throughout the text, and with the clear and concise instructions, it is difficult to make an error in construction. Total construction time is reasonable too—it

took me about seven hours to complete the VOM.

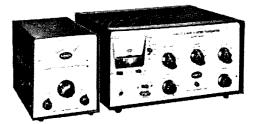

After the VOM was completed, I was very interested to find out what kind of repeatability and meter linearity I could expect. Using W2DXH's voltage calibrator (see his article in this issue), I was able to accurately measure the linearity of the meter movement. It was remarkable, in fact, almost unbelievable! At

Knight-Kit I	(G-640 Specifications
DC Sensitivity:	20,000 ohms per volt or 10,- 000 ohms per volt (function of scale multiplier switch).
Accuracy:	Within 3% of full scale reading on DC to 1600 volts; within 5% of full scale reading on AC to 1600 volts.
Frequency Response:	20 Hz to beyond 200 kHz.
DC Volts:	0 - 0.8 - 1.6 - 8 - 16 - 40 - 80 - 200 - 400 - 800 - 1600 - 2000 - 4000 volts.

Div. of Aerotron, Inc. 178 HERRICKS RD., MINEOLA, L. I., N. Y. 11501

only one point from one end of the scale to the other did the meter deviate from a linear reading. At the five volt point on the 15 volt range, the meter indication was about 100 millivolts off. And 100 millivolts out of five volts is a pretty small deviation—so small it wouldn't even be noticed in the normal run of measurements.

Next the accuracy and repeatability tests. These were made using the same voltage calibrator. The accuracy of the meter proved to be extremely good. The DC voltage scales, as far as I could tell with my naked eye, were right on the money. Same with the AC ranges. The resistance ranges were checked out with precision 1% resistors; in every case they were very, very close to the known resistor value. Repeatability: I couldn't detect any difference in readings when making the same voltage measurement several times. A 10 volt source showed up as exactly ten volts on the meter each time I put the probes across it.

If you're in the market for a VOM, you should definitely take a close look at the Knight-Kit KG-640. For accuracy, reliability, and dependability, it would be difficult to find a better instrument value for \$39.95.

SOUTHWEST SEMICONDUCTOR SPECIALISTS P.O. BOX 12312, SAN ANTONIO, TEXAS 78212

73 Looks at the Motorola HEP Line

Motorola's new experimenter transistors have many ham uses.

If you've been in a radio store recently, you've probably noticed a large display full of mouth-watering Motorola semiconductors. The display (and the items in it) are part of the new Motorola HEP program. The H, E and P stand for Hobbyist, Experimenter and Professional, and that's who the program is aimed at. The HEP semiconductors are designed for radio-TV servicemen, experimenters, schools—and hams. Naturally, we're most concerned about their ham uses, and they have plenty.

The HEP program means that now many common and exotic semiconductors with excellent performance are finally available at local radio and hobby stores-and at reasonable prices. The HEP line is very extensive; it even includes some digital integrated circuits and a field effect transistor. Most of the items are lower in price or about the same as competing experimenter-hobbyist transistors, but the HEP line is much more extensive. You can buy cheaper versions of many of the devices from industrial distributors under other names and in different cases, but the HEP line is widely available. That's a great boon to most hams even if it means that the transistors cost a few cents extra.

I've had a chance to try some of the HEP devices, and I've found them excellent. All the ones I've been able to check beat the specs Motorola publishes. Here's a quick look:

The HEP-1 is a "standard" PNP germanium mesa transistor. It costs 89¢ and is useful in most low power experimenter circuits: af amplifiers, if amplifiers, regenerative and superregen detectors, oscillators, etc. It easily oscillates to 250 MHz in a simple dipper I have.

The HEP-2 and HEP-3 are low power, high frequency germanium transistors. They have cutoff frequencies of 750 and 250 MHz and betas of 60 and 80.

The HEP-50 through 53 are 300 and 600 mW silicon PNP and NPN transistors for the HF and low VHF range. They are useful for everything from CPO's and meter amplifiers to low power transmitters. V_{CB} is listed from 10-20 V, so they're not suitable for most modulated amplifiers or other circuits with inductors unless you use very low voltage. Cost is 79¢ to \$1.29.

A group of recently announced transistors seems to have been added with the ham in

mind. They're four tiny silicon plastic transistors for VHF use. The numbers are HEP-54 to 57 and three are NPN, one PNP. Dissipation without heat sinks is 310 mW. Cutoff frequencies range from 30 to 750 MHz and beta from 70 to 180. Prices are \$1.08 to \$1.44. All four show very low input and output capacitance.

HEP-101 is a 10-V, 400-mW 95¢ zener, and HEP-102 through 105 are 1 W zeners for 3.6, 6.2, 9.1 and 12 V. They cost \$1.20 each.

HEP-151 through 162 are various silicon rectifiers rated from 1 A to 15 A and 50 to 1000 PIV. The 15-A ones are stud mounted, and come with mounting kits, the 3-A ones are top hats, and the 1-A ones are tiny (smaller than ½-W resistors) epoxy-cased units. As examples of prices, the 15-A, 50-V HEP-151 is 79¢; the 1-A, 400-V HEP-157 is 56¢; and the 1-A, 1000-V HEP-160 is \$1.45.

Especially interesting are the miniature (%" \times %") HEP-175 through 177 bridge rectifiers rated at 1 A from 50 to 400 PIV. They cost \$1.49 to \$2.25.

HEP-200, 230 and 231 are germanium power transistors. 200 and 230 are 3-A TO-3 cased units (about 85¢). The HEP-231 is a 15-A, TO-36 high power transistor. It comes with mounting kit and costs only \$1.69.

The HEP-232 and 233 are high power, high voltage units: 70 V, 7 A, 90 W and 65 V, 15 A, 150 W respectively.

HEP-250 through 254 are germanium PNP audio transistors, including a low leakage one.

HEP-300 through 307 are silicon controlled rectifiers (SCR's). These incredibly useful devices haven't been used much by hams yet, but we should see more and more of them. They make excellent switches and relays for vibrator replacement, speed controls, etc. The HEP units are rated at 5 and 15 A and 50 and 200 V. They come in both normal and reversed polarity with mounting kits for \$2.29 to \$6.20.

HEP-309 and 311 are triggers for use with SCR's. HEP-310 is a unijunction silicon transistor; its price is \$1.49.

HEP-553 through 558 are digital integrated circuits. See the article by W6GXN in the December 73 for some uses for them. They cost \$1.69 (for a bias driver, a fancy regulated power supply) to \$5.99 (J-K flip-flop).

Jack Morgan K1RA Greenfield, N.H.

Knight-Kit TR-102

Two-meter equipment has come a long way in the past 25 years. A look at the gear we used in the W.E.R.S. activity during WWII would make you shudder: modulated oscillators that drifted all around the band, and super-regen receivers that could radiate almost as much as the transmitters.

At a meeting of the Old Timers in Trenton, N.J., in 1946, the late John Reinartz, W1QP, showed us a five-tube, crystal controlled two-meter rf source, built on a 3 x 8 inch chassis. He plugged in a 4.5 MHz crystal at one end, and a small flashlight bulb lit up at the other. We were amazed that those receiving tubes could put out anything at all on two, especially with the final tube doubling. But we were progressing.

Things are very different today on two, and kits have little resemblance to those of the early days. One of the most interesting recent kits is Allied's Knight-Kit Model TA-102. Similar basically to the Model TR-106 that was

discussed by WA1CCH in the August issue, this one has an additional multiplier, and coils that are well designed for two. Output is a good 10 watts over the entire band with either VFO or crystal control. The Model V-107 VFO unit is an accessory that plugs into the rear deck and gives a very neat appearance along side the TR-102.

The instruction book gives you two chances to do everything right the first time: clearly worded text, with a picture to show exactly what is intended. You would almost have to make an error on purpose to get into trouble. The kit we assembled gave no problems and produced the expected output.

Here is a very inexpensive way to get on two meters with a good modern transceiver, ready for either mobile or fixed operation simply by using the appropriate power cable. We expect to hear TR-102's in ever-increasing numbers in round tables, emergency and mobile work. See you on two with a TR-102.

The HEP-801 is an N-channel field effect transistor for low frequency and dc uses. It costs \$3.39.

Also included in the HEP displays are heat sinks, IC sockets, TO-3 mounting kits and a number of books and pamphlets. A couple of the books are discussed briefly on page 87 in the October 73.

The prices quoted above may vary a bit

from different stores. You can get a complete list of HEP distributors and a catalog from Motorola HEP, Box 955, Phoenix, Arizona 85001. Incidentally, the new Allied consumer catalog lists the HEP-devices with their prices. Whether you order them by mail or buy them locally, try some of the HEP semiconductors. You'll like them.

... WA1CCH

A Junkbox Ten Minute Timer

Here is a ten minute timer which will serve as a reminder when its time to identify in those SSB contacts. If you have one of these you can give the kitchen timer back to the XYL and perhaps avoid a citation at the same time.

The circuit uses a 12BY7 to control a sensitive relay in the plate circuit, which in turn centrols a warning light to tell you when the time is up. The tube is normally in a conducting state and the light is on. When the normally open momentary contact pushbutton is depressed, a negative voltage, rectified by CR1 is applied to the grid of the tube, biasing it beyond cut off and extinguishing the light. At the same time the 8 µF capacitor charges to about 175 volts negative. As long as this capacitor remains charged sufficiently the tube can not draw enough current to energize the relay and turn on the light.

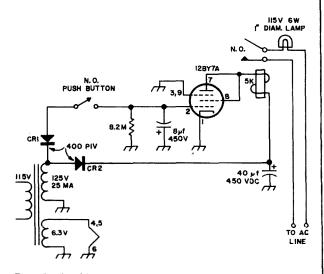

Fig. 1. Junkbox ten minute timer.

The capacitor slowly discharges through the 8.2 M resistor until after about 9.5 minutes the relay pulls in and the warning light lights. A push of the button starts the cycle over.

The discharge time of the $8 \mu \dot{F}$ capacitor is controlled by the value of resistance across it. The 8.2 M resistor shown gave a time of 9.5 minutes which was considered close enough. If the resistance is increased the time will be longer, if it is decreased, shorter. A change of one megohm will change the time by about a minute and 10 seconds.

Letters

More Non-Technical Articles?

Dear 73:

How about running a few not-so-technical articles in each issue of 73. You see, not every amateur is a Marconi or a De Forest; therefore, I suggest that you divide your magazine into three sections: one for the advanced amateur, one for the average amateur and, lastly, one for the so called "button pusher" type amateur. This way, I believe, all hams will be able to enjoy your publication, not only the experts.

Robert Mauro WB2UHY Whitestone, New York

Modern Hamming

Dear 73:

Just finished reading "Remove the Drudgery from Ham Radio." It is a great idea, but why bother with all that expensive equipment anyway? There is a very cheap way to do our hamming today—by telephone! S-9 signals, no QRM (except on party lines), no QSB, no TVI, no license tests, no unsightly antennas on the roof. . . . The telephone company will even keep a log for you (of out-of-town calls, at least).

Jerry Blakeslee WB2VUC Pitman, N.J.

Dissatisfied Reader

Dear 73:

Please enter my subscription to 73 for two years. I enjoy the construction articles and also the editorials. I would much prefer to see more articles, though, and less space devoted to letters from dissatisfied readers.

J. H. Shoemate WA6LTJ San Jose, California

Chess Cover

Dear 73:

My husband, WØYEG, is an ardent subscriber to 73 Magazine, and consequently, you can find one or more issues in almost every room of our house. I'm not particularly interested in ham radio, but I am interested in magazine covers and advertisements. Your covers are always attractively done but the November issue wins the prize! Hats off to the bright fellow who's responsible for this exceptionally clever cover! It ranks number one on my list and I have a feeling that it'll be a long, long time before any cover tops this one.

Lorrie Dodge Omaha, Nebraska

Microwave Propagation

Dear 73:

Received my copy of the November issue of 73 with the article "Amateur Microwave Propagation" and I'd like to offer the following comments.

On page 100, second column, 7th and 8th lines, I recommend against using two antennas to serve one transmitter since this will surely result in a "multipath" condition with fading and distortion being the result. The method is okay for receiving though.

On page 103, in the descriptive note for Figure 7, the formula for computing gain got a little gnarled in the composing room. It should read: Gain (in dB) = 20 log $f + 20 \log D - (52.6)$.

On page 104, in the notes for Figure 9, 3rd line from bottom of page, sine conventions, should read "... negative when the angle slopes up.")

Ray Thrower WA6PZR San Carlos, California

Horseflies

Dear 73:

Keep up the good work. You have a wonderful magazine. As an older man, and an advocate of "Law and Order", I am for the ARRL 100% but we certainly need 73! We need for Wayne to keep the ARRL from becoming too stodgy. You have already had an influence on QST—their journal has noticeably improved in the past few months, so please keep sniping.

Bob Bergner, M.D., K4JBK Louisville, Kentucky Dear Wayne,

It looks like the ARRL is trying to put themselves out of business. All this carping about home-made equipment and technical proficiency is beginning to get me down. After all, if the hams wanted to be professionals they would do so. Another thing that irks me is this retesting business. At least a dozen of my friends have pointed out that they got their licenses in good faith and now the implication is that they are a bum or a crook or something. I suspect that a good percentage of the old timers wouldn't even try to pass a new test. Ham radio can only service with numbers and we won't have them with a sword hanging over our neck. I've been in radio for over 36 years and I've never heard as much hate and discontent as these ARRL proposals have caused. QST wonders how come new licenses have fallen off . . . I feel for them.

Bob Wilson KIGVA Portland, Maine

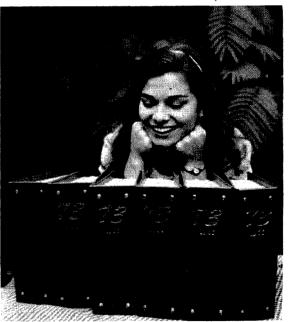

New Reader's Comments

Dear 73:

Just a day ago I wrote to raise the devil because I had been waiting over two months to get your rag after sending you my good dough. One day after it is in the mail box the rag arrives. I don't write letters and never did but after a glance at this I just had to drop a line for what it is worth. Sure I been hearing all the propaganda about you-what ham hasn't the past few years-well I got that 73 (finally) and doggone, I sat down with it and didn't get up till I went over it from cover to cover (cost me some sleep). Well contrary to what I had heard, I like the thing. The articles are really good. I enjoyed the rambling style—I like the construction articles—I like the Editor's Ramblings—I like Wayne's column "de W2NSD"-In fact I like the whole d--- thing so much I'm gonna try to gather up enough loot to try to get all the back issues in the near future. By the way, I do a lot of building (not the novice stuff), as I been in the game a couple of years myself, and I like the saddlestitching because I do use magazines on the work-bench to build stuff from articles. You got a new one on the string and I even would like a copy of you booklet "Writing for 73". A self-addressed envelope is enclosed and I am even putting a stamp on it. You might be hearing from me again and if the mags are all as interesting to me as this first one has been, you will have me around for a long time.

Keep up the good work. Some of us can appreciate it.

C. G. Stuart W8TZO
Toledo, Ohio

That's W7IDF's pretty daughter Thea admiring the 73 binders. Have you ordered the binders you wanted?

Technical Aid Group

The first members of 73's Technical Aid Group are listed below. They are willing to help other hams with their technical problems. If you have a concise question that you think can be answered through the mail, why not write to one of the hams on the list? Please type or write legibly, and include a self-addressed stamped envelope. One question to a letter, please.

George Daughters WB6AIG, BS and MS, 1613 Notre Dame Drive, Mountain View, Calif. Semiconductors, VHF converters, test equipment, general information.

Roger Taylor K6ALD, BSEE, 2811 W. William, Champaign, Ill. 61820. Antennas, semiconductors, product data, general.

Jim Ashe W2DXH, R.D. 1, Freeville, N.Y. Test equipment, general.

If you'd like to join the Technical Aid Group and you feel that you are qualified to help other hams, please write us and we'll furnish complete information. It's obvious that we need many helpers in all parts of the country and in all specialties to do the most good. While 73 will try to help with publicity and in other ways, we want the TAG to be a ham-to-ham group helping anyone who needs help, whether they be 73 readers or not.

Don Nelson WB2EGZ, EE, 9 Greenridge Road, Ashland, N.J. 08034. VHF antennas and converters, semiconductors, selection and application of tubes.

Tom O'Hara W6ORG, 10253 East Nadine, Temple City, Cal. 91780. ATV, VHF converters, semiconductors, general questions.

Stix Borok WB2PFY, high school student, 209-25 18 Ave., Bayside, N.Y. 11360. Novice help.

(Editor's Ramblings from page 4)

high gain antennas, and low noise stable transistor converters) have reduced the early problems of UHF quite a bit. After some flustering and discussion, Congress passed the All Channel TV Law, which requires all TV sets now sold in the US to be able to receive all 82 channels. The hope was that the public would buy enough new sets to insure that most people could receive all channels in a few years, though some claimed that the increased cost of the sets (UHF tuners add about \$20 or less to the cost of most sets) would ruin the TV manufacturers since no one would buy the more expensive sets.

These critics were wrong. Tax reductions and prosperity, plus the recent color TV set boom and the increasing number of two (or three) set families have caused such a turnover in TV receivers that it won't be long before most US families can receive all stations, VHF and UHF.

Then the time will come for the inevitable change that VHF broadcasters have been fearing: All TV must move to UHF. This will certainly not help their competitive position, but it will give them a few advantages: UHF TV is generally less bothered by ghosts and co-channel interference than VHF, and the wider

flat bandpass available at UHF often gives better reception of color TV than VHF. Also, UHF suffers no skip interference.

Vacating the VHF band will release 72 MHz for other services. Perhaps a few megahertz more should be added to the FM broadcast band, and legitimate users of CB deserve some VHF frequencies where they won't be bothered by skip. But a great deal of those frequencies should go to businesses. Perhaps 25 to 50 MHz wouldn't be excessive in view of the number of present and prospective users. With 10 kHz channels, that would be 2500 to 5000 channels.

This change would save the still-little-used VHF ham bands for the future when they'll undoubtedly become more and more important. It also would provide the vital frequencies needed for two-way radio without adopting such suggested stop-gap measures as using unused TV channels permanently.

Writing for 73

Would you like to try your hand at writing some articles for 73? If you would, we've got a small booklet, "Writing for 73," which you can have for a self-addressed business envelope. I've also made up a list of articles I'm looking for if you'd like that.

. . . Paul

What's New for You?

This is the first in our new monthly series devoted to short, timely items of interest to technical hams. We're going to concentrate on practical developments that are of use to hams now-or will be very shortly. Among the topics we'll cover are new semiconductors and circuits, other new components, newly available surplus, technical nets, technical meetings, and so forth. All items will give credit to the sender. Please get them in to us as soon as possible so all interested hams will be able to take advantage of them quickly. The deadline for an issue is the 15th of the second month preceding the date on the cover. For instance, items to be in the March issue should be here by January 15. Please keep your contributions short for this column. Long items should be submitted as articles.

Paul Franson WA1CCH

Motorola \$1 FET

If you have been neglecting to use field effect transistors because of their high cost, the new Motorola MPF103, 104 and 105 may be just what you're looking for. These new transistors cost \$1.00 in quantities up to 100 and are available through Motorola dealers. All of these devices have a maximum drainsource voltage rating of 25 volts, gate-source voltage rating of -25 volts and 200 mW dissipation. The only difference between the units is in the forward transfer admittance (y_{fs}) and zero-gate-voltage drain current (I_{DSS}). Typical values for the MPF103 are $I_{DSS} - 3$ mA, $y_{fs} - 3000$ µmhos; MPF104, $I_{DSS} - 6$ mA, $y_{fs} - 4000$ µmhos; and MPF105, $I_{DSS} - 9$ mA, $y_{fs} - 4500$ µmhos. The low value of input capacitance, typically on the order of 4.5 pF and the reverse transfer capacitance of 1.5 pF result in excellent operating characteristics well into the VHF bands. As a test, a 200 MHz Colpitts oscillator was constructed using these FET's. All of them worked well in the circuit; in fact, two of the devices out-performed a common five dollar variety. Excellent results were also obtained in a 3.5 to 4 MHz VFO using the Clapp circuit and in several rf amplifier circuits up to 50 MHz. Although I have not tried it, 1 suspect that these transistors might work well in a two meter converter.

Jim Fisk W1DTY

95¢ Fairchild FET

Fairchild's new 2N4360 silicon P-channel field effect transistor costs only 95¢ in small quantities. The low price is partly a result of its epoxy case. Maximum voltage for it is 20 V, dissipation is 200 mW, input capacitance is a maximum of 20 pF, and feedback capacitance is only 3 pF. Typical forward transconductance is 3000 µS (microsiemens or micromhos). This FET is designed for low frequency use, but shows some promise in the HF range.

WA1CCH

\$1 TI FET

There's been a lot of talk about the new Texas Instruments TIXM12 P-channel germanium field effect transistor. It's designed for VHF use—typical noise figure is 2 dB at 100 MHz. It sounds perfect for six and two meter converters as well as HF uses. The only problem is that it's not available. This seems to be the TIXM05 story all over again. When and if these very promising-sounding FET's become available, we'll let you know.

WA1CCH

15¢ GI Transistors

General Instruments has recently introduced a number of very cheap epoxy-cased silicon transistors. They're made in Taiwan and cost as little as 15ϕ if you buy a lot of them. Individual prices run a little more, but not much—about 40 to 50ϕ . These transistors are useful for many ham applications as amplifiers and switches. F_T is 200 to 250 MHz minimum, and they come in PNP and NPN pairs. Among them are the 2N4140-2N4143, and 2N4227 and 2N4228. They work well in general purpose applications.

New ATV Catalog

If you're interested in ham TV-or think you'd like to get interested in ham TV-you'll certainly want the new 1967 catalog from ATV Research. It's 20 pages thick and contains all sorts of gear of interest to TV'ers. Best of all, it's free! Send your name, address and zip code to ATV Research, P.O. Box 396, South Sioux City, Nebraska 68776.

TI Audio and AM/FM Handbook

Texas Instruments has just published a new book in their useful handbook series. This one is about the design of audio amplifiers and AM/FM tuners. While it's devoted to consumer applications, it's obviously also very useful to the ham who designs. The book is thoroughly practical; it even gives photos and printed circuit board layouts for some receivers. The name is Audio and AM/FM Circuit Design Handbook and it costs \$3. You can buy a copy from any TI distributor or from TI Technical Publications, MS75, P.O. Box 5012, Dallas, Texas.

Amperex Audio Slide Rule

Here's one of the cleverest and most useful gadgets we've seen in some time. It's a handy slide rule for audio circuits. One side (shown in the photo), shows a basic audio system with a slide that gives the proper parts values for different transistors, power levels and voltages. The amplifiers range from a one watt, 9 volt amplifier to a 12 watt, 28 volt one. All use the excellent complementary symmetry circuit which provides excellent results with no transformers. The back of the rule is a more conventional slide rule for designing audio circuits. Any audio designer should have this rule. It costs only 50¢, and is available from Amperex Semiconductor Division, 230 Duffy Avenue, Hicksville, N.Y. 11802.

Aladin Breadboarding Kit

Aladin Kits has introduced a new bread-boarding kit that should fill the needs of just about all electronic experimenters and hams. This kit contains a punched phenolic deck, an aluminum mounting base, several brackets for mounting switches, pots and transistor sockets, silver plated solderless connectors and an assortment of assembly hardware. The terminals contained in this kit are designed so that circuit connections may be made easily and efficiently without soldering. This is extremely helpful when designing and building circuits. For more information, write to Aladin Kits Company, 21011 Dequindre Road, Hazel Park, Michigan 48030.

New Meshna Catalog

John Meshna's just published a new catalog. You'll eat your heart out looking at his goodies contained in this fat 72 page book. Meshna's catalogs certainly must be the best surplus catalogs around; he doesn't just list the gear with prices, but tells you what it's good for. He writes with much wit, too. You've got to get this catalog; send John the 25¢ today. You'll hate yourself otherwise. Meshna, 19 Allerton St., Lynn, Mass.

Building Your Amateur Radio Novice Station

Most beginners will tell you that the hardest thing about ham radio is getting started. In addition, many of them say that most articles and books describe equipment which is either too complicated or do not furnish sufficient construction details. Howard S. Pyle. W70E, has put together a construction manual for building an amateur novice station with the complete details that many people have been looking for. YB Pyle describes a professional-looking transmitter and receiver which cost very little to build. They have been thoroughly tested for ease of construction and for on the air performance. Nothing is overlooked in the construction phase; full size drilling and cutout templates for chassis and panels are included within the pages of this book. They may be fastened directly to the chassis and panels and used as a guide for drilling all the necessary holes. While the completed equipment has been specifically designed for the novice operator, it will serve the General-Class amateur as well. The price of this new book is \$3.50, and it is available at your local distributor or from the publisher, Howard W. Sams & Company, 4300 West 62nd Street, Indianapolis, Indiana 46206.

Heath's New Single-Banders

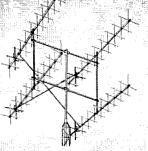

When Heath announced their single-band SSB transceivers a few years ago, no one could believe their low price of \$120. Now they've improved the already-excellent transceivers and reduced the price! In addition to all of the features we already know about-low cost, small size, high performance, easy construction -they've now added front panel selection of sidebands, improved audio and AGC, mike and gain control, more convenient front panel arrangement, a mode switch position for the optional 100 kHz calibrator, ALC input for use with linears, and power connectors and up-dated styling to match the SB-line. And the prices: \$99.95 for the HW-12A (75 meters), \$104.95 for the HW-22A (40 meters) and HW-32A (20 meters). Write to Heath, Benton Harbor, Michigan for more information.

Transistor Circuits

K. W. Cattermole's Transistor Circuits is a very good circuits reference book which would be an excellent addition to any serious amateur's library. The circuit descriptions in this new edition of a well known volume (in engineering circles) are clearly written and not highly mathematical, although a working knowledge of algebra is helpful. It gives a clear insight to circuit operation and provides the reader with much practical, useful, and worthwhile design data. The 70 page chapter on high frequency amplifiers should be particularly interesting to hams. This chapter is very well done and covers internal feedback and neutralization, gain limiting and multistage amplifiers, coupling networks and wideband amplifiers. Other chapters cover bias supplies and stabilization, power amplifiers, oscillators, modulation, detection and mixers, and binary and computer circuits. In addition, six appendices contain data, although quite mathematical, of use in detail circuit design. This book is highly recommended for the amateur with a strong technical background. \$14.50 at your bookstore or write to the published, Gordon and Breach, 150 Fifth Avenue, New York, New York 10011.

VHF/UHF ANJENNAS

FOR MORE DX PUNCH

The standard of comparison in amateur VHF/UHF communications. Cush Craft antennas combine all-out performance with optimum size for ease of assembly and mounting at your site. They can be mounted vertically, horizontally, in pairs, quads, or virtually any combination allowing you to design the antenna system to meet your exact requirements.

- Planar epitaxial integrated circuits for reliability. No tubes—No separate transistors.
- Precision feather-touch key built-in.
- Fully digital—Dot-dash ratio always perfect.
- No polarity problems—Floating contacts switch 1-amp.
- Rugged solid construction—will not walk.
- Send QSL or postcard for free brochure.

PALOMAR ENGINEERS

BOX 455, ESCONDIDO, CAL. 92026

the U.S.

Fellows listening to some of the ridiculous pile-ups on 20M may think I am off my beam, but I've done enough working from the rare end now to speak with some authority on the problem. The DX operator, I feel, is entirely responsible for any mess that builds up. It is his show and he can run it as he wants. Through a lack of experience or stupidity he can allow fellows to break in on him, tail end, or call endlessly. The sharp op can size up the crowd for him easily, as I pointed out last month. If he is operating transceive. . . . I'm speaking primarily of sideband now . . . he can work fast break-in, allowing no more than five or six seconds for callers. If he wants to see how many are waiting he can ask for one call from all waiting and see how finely he has to break down the group to get individual call letters through. Usually the band is open to certain call areas or countries and these can be broken down into prefixes on fast breaks ... WB2, WA2, etc. If the fifth area is weak a simple request for fives is enough. Ditto calls from other countries, which can be handled exactly the same.

The major problem is how to get the DX stations to operate efficiently. I've tried to explain to them over the air and almost without exception they continue on doing exactly as they were before, grumbling about the QRM and making one contact every few minutes.

More Safari

OK, sports fans, I'll try to carry on my narrative from the October editorial. Mind you, ham radio plays a small part of the following so buzz off if you read True or Sports Afield and get your thrills there.

During the first two weeks of our hunting Larry and I had taken turns shooting, with one of us waiting in the Land Rover while the other went out and stalked the game. This had gotten to be quite boring and we decided to try going out on alternate days and see how that would work. Larry (WA6TCI) went out the first day with Jim (W5PYI) along to take pictures while I sat back at the "hotel" writing my October editorial. This kept me pretty busy for the day with just enough time to hike the half mile into Nanyuki and look the town over carefully and buy a couple of Ruark books (Something of Value and Uhuru, both of which I recommend most highly).

On Sunday it was my turn. I was worried . . . Larry had been out shooting zebra all day Saturday. He'd gone out at 6:30 in the

morning and come back at 8:30 with two nice zebras. He'd gotten up to about 60 yards from a herd for the first one and 100 yards on the second. In the afternoon Larry came back for lunch and reported that the herds were now quite alert and he wasn't able to get in close for another shot. Just before dinner he and Freddy, our White Hunter, closed in on a good sized herd and Larry shot at a good specimen . . . then Freddy shot . . . no results . . . they both shot several more rounds into the rapidly disappearing herd and brought down one little foal as the only casualty. Very embarrassing.

Sure enough, when I went out on Sunday the zebra were very spooky and we just couldn't get close to them at all no matter how we tried to sneak around. In desperation I tried a very long shot after an hour and a half of tracking a herd . . . I missed. We followed them for another hour and a half and then gave up and went back to the hotel for breakfast.

Hiking through the brush at a crouch for three hours at 6000 feet elevation is particularly tiring. After breakfast I snoozed for a half hour to recoup. At 10:30 we were off again driving through the thousand acre paddocks looking for zebra herds. It is amazing how difficult those brightly striped animals are to see at a distance. Nothing in sight. We took off on foot again and by 11:30 we had a small herd in sight. Ten minutes later I was within shooting range and carefully drew a bead on a large stallion . . . wham! I missed. Rats!

Kerede, my gun bearer, followed the herd with me racing along behind him. I don't know how he knows which way they've gone, but we veered this way and that with nothing whatever in sight and in ten minutes had them back in range. I wasn't going to miss again, you can be sure. I steadied the gun against a thorn tree and settled down for a very careful shot . . . about 150 yards . . . nothing to it. Blam! Off they went, another miss. I must have a subconscious wish to spare zebras. This is ridiculous . . . and very humiliating.

We went back to the car and started looking again . . . aha, a good sized herd of zebra over across that large open plain. Kerede and I got out and stalked through the bush on the edge of the plain while the car continued on as a decoy in the other direction. As we got in closer we could see they were still grazing calmly . . . then suddenly a raucous cry from two "get away" birds rang out above us . . . get away . The zebras did.

After a late lunch and an afternoon siesta we went out for one more try. By 5:30 Kerede and I were trailing a herd of zebra mixed with impala . . . this was a spooky group and we just couldn't get in close. I fired one shot at 130 yards as they started off again for my third miss of the day. So much for Sunday.

My marksmanship just wasn't that bad, I knew, so I began to suspect that something was amiss with the gun. Larry, back at the hotel, agreed. His shots the previous night had been easy ones too and he still had missed. Obviously something was wrong with the sighting scope.

Monday at mid-morning Larry returned with another zebra, this being his day for shooting. That's four for him, counting the foal they'd bumped off by accident . . . and I haven't gotten a one. Say, what about the sighting on the rifle? Oh, they'd checked that and it was perfect. So much for our excuse for missing. Larry went back out after zebra again, but they were wise by now and he never got another shot at them the rest of the day.

Secret Valley

Most of us have heard about the Tree Tops Lodge in Kenya, a hotel built among the tops of the trees where visitors can watch the wild game coming to feed. Shamsu Din has built his own version of Tree Tops up on the side of Mount Kenya at about 8000 feet and calls the little glen and pond it overlooks Secret Valley. We all drove up there for a night to have a look at the leopards which come there every night to feed . . . Larry's zebras being the meal for this evening.

To get to the lodge you drive by Land Rover up the side of the mountain and park in a small clearing and then hike a couple hundred yards along a small trail through impenetrable forest. The bamboo and vines grow around 200 foot high trees with not enough room for even a person to get through. It was dark and alarming going down the trail, but the hotel guests were reassured by Shamsu standing guard with his big rifle and full cartridge belt. Larry and I weren't so happy because we knew that those bullets were the wrong size for the rifle and the whole thing was for show. Shamsu wouldn't let us bring our rifle . . . we'd been teasing him too much about popping off one of the leopards that come in to feed.

On some nights they have as many as eight or nine leopards turning out to feed on the platform just about twenty feet from the porch

of the lodge. They have lights rigged up so visitors can take pictures right up close. I was all set with my super telephoto, but only one leopard slunk around this night and he never got up in the light. I did get some pictures of bushbuck and water buffalo though.

Secret Valley Lodge is rustic. The rooms are very simple: rickety bed, table, lamp and a couple of hooks on the wall for your clothes. The rates are \$14 a night, but you can strike a bargain with Shamsu if he isn't filled up. I have yet to meet an Indian that you can't bargain with . . . it seems to be part of their heritage. I've met few that I didn't have to bargain with.

Our separate day arrangement for hunting didn't work out very well for Larry, I had no problem keeping myself amused on my day off with writing, horseback riding and things. But Larry had nothing to do and while I was out hunting on Sunday he sat around the hotel with his teeth in his mouth and got bored silly. He and Jim walked down town Nanyuki, but there was nothing to do there but watch haircuts. They tried taking pictures of the town, but every African that happened to be within camera range came over and demanded a shilling. By Sunday night Larry and Jim were ready to go back to Nairobi rather than face another day like that.

Ignoring my carefully laid plans and hotel reservations for the rest of the trip they took off Tuesday morning for Nairobi, leaving me to hunt for two more days by myself. Well, OK, I've still got special licenses for an oryx and an eland, perhaps I'll get one or both. I can meet then in Nairobi at the end of the week and get back on schedule. And I still want that zebra.

Piga Punda

Up at 6 . . . dress in my bush pants and shoes . . . shirt and bush jacket to ward off the cold, 50° this morning. Pour the tea in the sink . . . no way to prevent the boy from bringing it in the morning and I don't want to make them unhappy by not having it appear to be drunk. Freddy arrives with Kerede and Labun . . . we're ready to get a punda (zebra).

After an hour or so of bumping along through bush country without nary a speck of zebra hide showing we pulled up at a native hut and, after a lot of fast Swahili discussion, one of the Africans led Kerede and me into the bush on foot. Inside of ten minutes we've spotted a herd. Kerede isn't taking any chances on my marksmanship this morning, he guides me in close. The zebra are uneasy . . . they

move off a bit . . . we follow, freezing when they look our way. They move off some more, we sneak along, hiding behind one inch thick trees. I take very careful aim and get off a shot at about 90 yards. The zebras take off immediately at top speed, but Kerede says piga (hit) . . . and off we go after them. Within five minutes we have them in sight again and the one I hit is limping badly. I aim carefully again and drop him. He is a big fellow with a beautiful skin.

We tried to follow the herd for another shot, but they weren't about to let us get within 200 yards. The afternoon was just as non-productive. Freddy had to get on to another safari, so he and his bearers were replaced by Prince Sam Sapieha (from Poland) and his bearer for my last two days of hunting.

How to Shoot an Oryx

Sam and his bearer Katimba joined me at 6:30 the next morning and, after checking my rifle out on the rifle range to make sure that it and I were shooting OK, we headed into the zebra territory for one more zebra try. Sure enough, there they were, a half mile away. We got out of the Rover and stalked them carefully. Just as we got to about 150 yards from them they melted away. We couldn't figure how they had spotted us so quickly when an African walked by . . . he had scared them off, not us. We tracked them for an hour and a half more, but they were with some impala and we just couldn't fool both groups at once.

After a fast breakfast at the hotel we packed a lunch and headed for the Napier ranch about 35 miles from town to look for my oryx. Frankly, I wasn't too sure what an orvx looked like. I think that I bought the license for one because Shamsu was dinning in my ear that he could guarantee me one. The license was only \$3, so I said what the hell and bought the extra license. Same for the \$11 eland.

I'd worked my way down the list of animals my license permitted me to shoot. I passed up the cute little dik dik and steinbok because they are so tiny and both live in mated pairs rather than in herds. I'd gotten one tommy, two impala, a waterbuck and one zebra. The license did permit me another tommy, two grants, another waterbuck, a bushbuck, a reedbuck, a couple more zebras, crocodile, wildebeeste and warthog . . . some other time perhaps . . . let's get on to the oryx.

Just after 11 we picked up one of Napier's boys and headed out into the paddocks looking for oryx. He knew right where they were

MUFFIN FANS

- ADVANTAGES: ★ Longer life for electronic tubes ★ Better regulation
- Retter regulation
 Keeps components cool
 Quiet, compact, easy to mount
 Maintenance free
 Prevents drift problems
 Can be used for exhaust or cooling

- Many practical uses

Can be mounted in the cover of most transceivers such as the KWM-1-2 series. S line series, Drake and many others Size: $4\cdot11/16''$ sq. x $1\cdot1/2''$ thick. 115VAC 60cy. Worth many times our low price. Checked and guaranteed USED EXCELLENT CONDITION. Only \$5.50 postpaid.

VHF TRANSMITTER CHASSIS (RF deck only) can be used as a complete transmitter capable of 4 to 6 watts output, or as driver for a 100-200 watt amplifier. Power requirements are 6.3 volts AC/DC @ 5A and 250/300VDC @ 100 ma. The unit will operate on the following ranges of primary frequencies:

- (1) 30-45 MHz (2) 60-90 MHz The unit was intended to be used as follows: (3) 90-135 MHz
- (1) 1st half of 12AT7 used as xtal oscillator w/6MHz xtals
- (2) 2nd half of 12AT7 used as doubler to 12 MHz
- (3) 2-5763's 1st as a tripler to 36 MHz, and 2nd as a multiplier (probably doubling to 72 MHz)

All amplifier stages operate class "C" indicating plate modulated AM

The unit can be used on 28 MHz, 50 MHz or 144 MHz amateur bands. It was used in aircraft communication units.

The unit is less tubes. Needed are 2-5763 and 1-12AT7 tubes. This unit sells for \$3.95 postpaid.

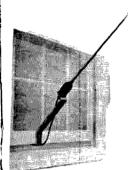

PANEL SWITCHING UNIT: Contains 4 4PDT center-off switches PANEL SWITCHING UNIT: Contains 4 4PDT center-off switches (telephone type). These were mfg. by Switchersft, and are the 16000 series. The contacts are rated at 3 Amps. 300 Watts AC. Included on the same panel is a Cannon microphone recepticle (female type). It is an XL-3-13 type. One Switcheraft phone jack is included. All units are brand new Large quantity in stock. Ideal for Hi-Fi, communications and many other uses. ONLY \$3.50 each PP.

INSCHO'S ELECTRONICS

Owego, N.Y. 13827 Box 21, R.D. 1

and we soon spotted them off in a nearby 1000 acre paddock. We had to drive about three miles to find a gate into that area. The oryx caught on right away to us and we could see them off in the far far distance through our glasses. As we drove they kept moving and we didn't get any closer to them. OK, we're not going to be able to approach them in the

Plan two was for Sam, Kibruto (the skinner) and I to hide behind a bush and wait for the oryx while Katimba drove the Rover around the edge of the paddock to keep the oryx moving. This plan broke down right away. We had no sooner gotten settled for our wait when the Rover was in deep mud and just barely able to work its way out. The roads around the paddock were impassable.

OK, plan three. Sam, Kibruto and I set up a blind made out of a couple of dead thorn trees and lav down behind it to watch while Katimba and the Napier boy tried to herd the oryx toward us. We waited about 45 minutes. whispering softly and flicking adventurous ants off our clothes, but no oryx. Katimba returned to tell us that the oryx refused to be herded . . . they just wouldn't pay any attention to them at all. They are probably used to the Africans herding cows and bulls through the paddock.

Plan four next. In this one I was to follow Katimba closely so the oryx wouldn't see me until it was too late. After a mile or two of sneaking along behind Katimba it became obvious to all of us that the oryx had no trouble at all telling the difference between an African and a European at 500 yards. They weren't fooled one bit and they hauled out as soon as I slouched up.

It was after 2 and I was quite ready for lunch. This hiking through thorn bushes is rough. You have to watch every tree closely so you don't get one of those 2" thorns jabbed into you, and they stick out all over. The ground is spread with the thorns too, many of them carefully pointed up to be stepped on. They will go right through most shoe soles and give a nasty infection. In the bogs I had to jump from one grass tuft to the next with memories of all those African movies where fellows disappear in quicksand going through my mind.

A few impala sandwiches washed down by some Schwepps fruit punch called Schwop got me ready for plan five. Africans, by the way, don't each lunch . . . they just squat and talk while the white bwanas eat. Two more Napier boys had joined us by this time so Sam decided that he and I would hide behind a bush in the middle of the paddock and everyone else would try to get the herd moving toward

We picked a nice bush, removed as many of the thorns lying around under it as we could, and settled down to wait, finding a few missed thorns the hard way. There is no position that is comfortable for long and 1 found myself shifting around every few minutes trying to distribute the ache. We could, after a half hour, hear the boys whistling at the oryx, but nothing came in sight. Aha, some horns began to show above the thorn trees not far away ... here they come. I got all ready and aimed carefully where I expected them to come out. A huge animal came out . . . that isn't an oryx, that's a Brahman bull. I wasn't sure what an oryx looked like, but I knew this wasn't it. The oryx went off in another direction while a herd of bulls went past us. We got up, brushed off the ants and made our way to another bush over toward the oryx. Suddenly about twenty of them ran across a clear spot about 150 yards from me. I figured I had about a 50% chance of getting one so I waited. hoping we could get closer. I knew that one shot would be all I would have.

Katimba motioned for me to follow him and we headed off at an angle to the herd and I got set for another try about 500 yards farther on. Just as I was settled down they poured out in the open and I got my first good look at them. I picked out a big one and aimed at his heart . . . wham! The herd took off instantly and mine was down, struggling to get up. I walked in carefully, knowing that these animals can be very dangerous when wounded. They have very long, very sharp horns and know how to use them. A second shot in the neck ended the struggle. I'd gotten my oryx.

Note

I wanted to find out what the reaction was to the first part of this hunting trip in the October issue before I inflicted more on you. The reaction was enthusiastic, hence my continuation this month. There'll be just one more day of hunting to cover next month and then I'll tell you about my visit to the 5Z4 boys and up into Uganda and Tanzania. I also want to give you some thoughts on the prospects for this section of Africa and how this may affect amateur radio.

If you don't get bored, I'd like to tell you about my interesting visits to the other countries in Asia and the South Pacific. I stopped in 26 this trip all told.

. . . Wayne

Keep your 73's neat and clean

Why should you have to root around in a stack of magazines to find those articles you need in back issues of 73. These well-made, attractive, convenient binders are made just for 73. They hold a full year—12 issues—of 73 where you can easily use them. They're inexpensive, too, and only cost \$3 apiece for each binder: 1960-61 (holds 15 issues, Oct. 1960-Dec. 1961), 1962, 1963, 1964, 1965, 1966. Include postage if you order only one, but two or more are postpaid in the U.S.A. and Canada. Include full postage elsewhere.

NCX-5 Mark 22 and NCL-2000 in factory sealed Cartons NEW \$1000.00 AC Supply \$95.00. K7HYZ N. 308 Locust Spokane, Washington 99206.

FOR SALE! Collins 75A-4 receiver, Collins KW-S1 transmitter and power supply, all for \$1200 or best offer. Heath 6 meter transceiver HW 12, with Hustler antenna, \$140. Heath TC-2 tube checker, \$25; Heath Visual Aural Signal Tracer Model T3, \$10; Heath RF Signal Generator SG8, \$15; Heath fm test oscillator FMO-1, \$25; Eico oscilloscope #460, \$50; Eico Battery Eliminator #1050, \$30. Make offer to Dr. Roger Simmons, WA4UDG, 621 Seattle Drive, Lexington, Kenfucky.

QSL CARDS???? "America's Finest" Samples 25¢. Sakkers Printery, W8DED, Holland, Michigan.

FOR SALE: Have complete set of unused, repeat unused, equipment as follows: Hallicrafter SR150, 12VDC power pack, Mosley D4-BC-A antenna, V-4-6 80 meter coil, Hallicrafter speaker, Shure mike and other accessories. Contact Don Mosley, Box 1552, Waco, Texas. Telephone Swift 9-2491.

\$12.95 W2AU \$12.95 • FOUR PURPOSE BALUN

The Balun Everyone has been waiting for. Will Help a TVI Problem. • Broadbanded 3-32 mc. • Center hang-up hook for inverted Vees. • Handles full legal power, 2KW PEP • Built-in lightning arrester • 50239 RF connector for coax transmission feed line eliminates center insulator • Withstands up to 600 lb. antenna pull • For use stands up to 600 lb. antenna pull • For use with all type antennas fed with unbalanced coax line. • Weighs only 6½ oz. 1½" diam. 6" long 2 Models: 1:1 matches 50 or 75 ohm unbalanced coax to 50 or 75 antenna load. 4:1 matches 50 or 75 ohm unbalanced coax te 200 or 300 ohm antenna load. • Helps eliminate TVI.
• All New W2AU Super Vinyl 2 el 10-15-20 quad. • Complete \$64.95 • W2AU Super Fiberglas 2 el 10-15-20 meter quad. Complete quad \$99.95 UNADILLA RADIATION PRODUCTS

HOT? COOL OFF with these BLOWERS.

115v, 60 cycle, 6/10 amp, 3400 RPM, with squirrel cage. Throws 100 CFM plus, Unused, repainted, Very Very quiet, No vibration, Shipping wt. 5 lbs. \$6.00

Dual squirrel cage blower, 115v. 60 cycle, 6/10 amp. 1570 RPM Redmond motor; with thermostat (cut-off 160 degree F); 2 speed (summer-winter) switch; quick disconnect. 5 ft. line cord. NOISELESS—no vibration, BRAND NEW. Shipping wt. LBS. \$7.50

24v DC, 4/10 amp, 10 to 13,500 RPM, 24 CFM. Rubber blade fan. Works at $\frac{1}{2}$ speed and CFM at 12v DC. Take outs, good. 2 LBS. \$1.75

115v 60 cycle, shaded pols phono-motor, with metal blade. Very quiet, beautifully balanced, NEW, 3 LBS, \$1.95

TOROIDS

 $88\,$ mhry, (two $22\,$ mhry on one core, wire in series), $5\,$ on an assembly, shipping weight 1 LB. $\$2.00\,$

20 microhry, $\%_4$ " 0D, 1/2" ID, 1/2" wide, A bargain, for the cores only. Shipping wt. 1 LB, 12 for \$2.00

All orders, except in emergency, or I'm at a hamfest, shipped same day received. For free "GOODIE" sheet, send self-addressed. stamped envelope—PLEASE, PLEASE include sufficient for postage, any excess returned with order. I carry private (Travelers) parcel post insurance, for domestic parcel post. For items too heavy, or too large for parcel post, 1 suggest bus parcel express. Please advise name of bus line, and city, where you can pick up the shipment.

Telephone 312 CAlumet 5-2235 2333 S. Michigan Avenue Chicago, Illinois 60616

ALL BAND TRAP ANTEN

Reduces Interference and Neise en All Makes Short Wave Receivers. Makes World Wide Reception Stronger. Clearer en All Bands!

Far ALL Amateur Transmit-ters. Rated at 1000 Watts AM 2000 SSB PiNet or Link Direct Feed. Light, Neat, Weatherproof.

Complete as shown total length 102 ft. with 96 ft. of 72 ohm balanced twinline. Hi-impact molded resonant traps. (Wt. 3 oz. 1" x 5" long). You jost tune to desired band for beamlike results. Excellent for ALL world-wide short-wave receivers and amateur transmitters. For NOVICE AND ALL CLASS AMATEURS! NO EXTRA TUNERS OR GADGETS NEEDED! Eliminates 5 separate antennas with excellent performance proven. Inconspicuous for Fossy Neighborhoods! No HAY-WIRE HOUSE APPEARANCE! EASY INSTALLATION! Thousands of users.

SEND ONLY \$3.00 (cash, ck., mo) and pay postman balance COD plus postage on arrival or send full price for postpaid delivery. Complete installation & technical instructions furnished.

never say die

Stanford Report

I tried to get a copy of this from Huntoon, but was refused, arousing my suspicions about it a bit. I still remember that lovely report they bought with your money from a public relations firm a couple years back which showed that QST was the only place to advertise and that virtually no ham had ever heard of 73. Fortunately this was so far out that few people paid it any heed.

Well you've spent \$21,000 on another report fellows. The first leak on the report says that they have found that 0.4% of ham operations are on TV and 3% on RTTY. Now you know that I am gung ho on these two modes, but I would never try to fool even the most gullible that there are 400 ham TV stations going or 3000 RTTYers batting it out at any time. Their 36% AM vs 19% SSB will take a lot of explaining to anyone who has operated on the ham bands within the last five years . . . make that ten.

The DXers Magazine

Gus, despite all warnings from friends, has decided to put out a DX magazine. The first issue came out back in September and the magazine has now settled down to an interesting, usually weekly, publication, running about 20 pages. I would say this, if you like to work DX now and then you are missing a lot of the fun if you don't have this little magazine coming in. It costs only \$8.50 a year by first class mail to US, Canada and Mexico. You'll know just what is going on all the time and all the latest scuttle.

Note for authors

Reputable magazines, almost without exception, pay for articles when they accept them for publication. I've been getting more and more complaints from ham authors about not getting payment for articles pub-

lished in other ham magazines. What can we do, they ask. Well, first of all, if I may be sarcastic, be a little more careful where you send your articles in the first place. If, however, you have submitted your article to us and we have, through sheer stupidity, rejected you, then, to get even with us for our denseness, you have forwarded your gem to another magazine and these clouts, after holding it for a year and a half, which, whether you like it or not, is par for the course, you find that you still have not been 'paid on publication" and you don't seem to get answers to your letters asking what is and where is my money then, I suggest, you write an explanatory letter to the post office department of mail fraud explaining the details of this attempt to mulct you through the U.S. mails.

Magazines exist only because they have second class mailing privileges and the appearance of a postal inspector in the publication office is reason enough for several cases of diarrhea, ague, ulcer, and housemaid's knee. I think you'll get the dough pronto. You get it two years or so earlier if you deal with 73 . . . unless we reject you.

Around the world with Wayne

Having worked Rasheed, YK1AA, a couple of times on twenty I was particularly anxious to visit Damascus and say hello to him. Jim (W5PYI) and I drove from Beirut to Damascus in a rented car, detouring for a few hours on the way to see the most remarkable ancient ruins at Baalbek, way out in the hinterlands of Lebanon.

Border crossings in the near east are an adventure. Jim worked the car patiently through the jam of cars while I used every New York subway trick I knew to work my way through the mob of people waving passports, exit forms, entry forms, automobile forms, and money at the nonchalant

(Continued on page 118)

Editor's Ramblings

Paul Franson WAICCH

You probably noticed a few changes when you received this issue of 73. In the first place, we've addressed the magazine on our new IBM data processing system rather than the mimeograph-type stencils we have been using. The IBM system is faster and more legible, and reduces the amount of manual labor involved in processing subscriptions and renewals considerably. We've been growing at an average rate of about 1000 per month for the past year and some, and we were outgrowing the old system. After all the bugs are straightened out, we expect a worthwhile improvement in the speed and ease with which we handle your correspondance.

However, in a change such as this one involving about 50,000 individual addresses, some mistakes are bound to occur. We regret these mistakes and want to get them straightened out quickly. You can help us in this. Please check the address label on your wrapper very carefully. If it contains any errors that might affect your receiving your monthly 73, please send us both the improper label and the correction. It is par-

ticularly important that your zip code be correct. If it isn't the Post Office may not deliver your magazines.

If your address label contains a minor mistake such as a mispelled name or wrong call, we'd appreciate your not asking us to correct it now. The next time you renew or change your address it will be easy to correct, but we'd rather not have to correct these minor things until we've had a chance to cure the more important mistakes.

Another change is that we've switched to a perfect binding. In my editorial in the November 73, I discussed the types of bindings for magazines and their advantages and disadvantages. I made a mistake in one term I used. CQ and QST are side stitched rather than perfect bound. Perfect binding doesn't use staples, so a perfect-bound magazine can be opened fully and it will stay that way. We feel that this binding overcomes the major disadvantages of both side stitching and saddle stitching, and hope you like it.

The third change this month is that we've switched printers. Since the September 1965

J R FINK W 26880 RFD 1 BOX U138 73 RINDGE NH 03461

Here's a typical address label. The name comes first. It includes one or two initials, and a last name of up to thirteen letters. Those of you with longer last names are perfectly justified in complaining about machines that don't have human feelings and so forth, but I'm afraid that we won't be able to use your full name. It won't affect delivery anyway. Next is the call. You'll notice that there's something suspicious about this particular one. It's irritating to have your call wrong, but we'd appreciate it if you would wait until you renew to ask us to correct it. It's also won't affect delivery of your magazines. The next line contains the street or box address and the expiration date. The first number indicates the month your subscription expires: I is January, 2 February and so forth up to 9, which is September. O is October, N is November and D is December. The second number gives the year your subscription expires: 7 is 1967, 8 is 1968, 9 is 1969 and so forth. If this space is blank, you have a life or advertiser's subscription, or something else special. The last line of the label gives the town, state and zip code. The zip is very important and must be right. If it's not, please send us both the incorrect label and the correct zip code. Incidentally, if you have an address that requires more than three lines, we can use it but it's not as convenient as the regular three-line address.

Getting Acquainted with Integrated Circuits

Darrell Thorpe 3110 N. 83rd Street Scottsdale, Arizona

Been looking for some practical general data on using integrated circuits? Here's a short introduction complete with circuits for inexpensive IC's.

If you are going to keep abreast of the most modern solid state circuitry, it's time to start thinking about using linear integrated circuits. Motorola and RCA have recently made available, off distributor shelves, monolithic integrated circuits suitable for operation up to about 100 MHz. And, the best news is that these latest solid state innovations are well within the pocketbook of the average ham. The introductory single piece price of these high frequency devices is in the \$4-5 dollar range. (RCA has just announced a 40% price reduction so the price will be less than listed in the catalog.) RCA is also offering an FM if amplifier limiter integrated circuit containing ten transistors and a voltage regulator for only \$2.00 and an integrated circuit amplifier-discriminator with twelve transistors and regulator for \$2.65.

However, the two circuits that look the most promising for ham use from the price and versatility viewpoint, are the Motorola MC 1550 and the RCA CA 3005. Both of these devices are broadly classified as rf-if amplifiers, and either one is useful at frequencies from dc to beyond 100 MHz. They can be used with an external tuned circuit, transformer, or resistive load in applications

such as:

A-Mixers

B-Wide and narrow band amplifiers (r-f, i-f and video)

C-Oscillators

D-product detectors

E-low-power modulators,

and probably many more with the application of a little ham ingenuity.

I don't wish to leave the impression that the devices mentioned are the only ones available. Similar devices are made by other manufacturers, for example, Westinghouse and Philco, to mention a couple, and also there are a host of other linear integrated circuits broadly classified as de amplifiers,

audio amplifiers and video amplifiers. Fairchild has just announced the availability of the μ A 703 rf amplifier with specification and price in the same range with the Motorola and RCA devices discussed in this article. Moreover, as I will get around to later, some of the low-cost digital integrated circuits can be extremely useful for rf purposes.

Circuit Operation

Now, let's get down to details, first as to what is inside these integrated circuits, how they function, and then, some typical

The MC 1550 and the CA 3005 are quite similar in construction and operation, in that both use a balanced differential amplifier. A simplified schematic that can be used to get familiar with the operation of both integrated circuits are comprised of three devices is shown in Fig. 1. Essentially, these integrated circuits are comprised of three transistors. The current to the emittercoupled differential transistor pair is supplied from a constant current sink transistor.

The voltage V₂ and resistor R₅ establish

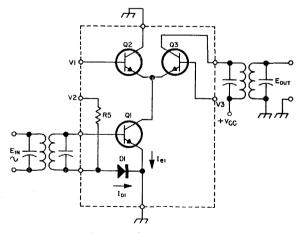

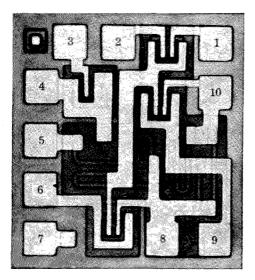

Fig. 1. Simplified schematic diagram of integrated circuit rf-if amplifier.

the current In in diode D1. Since D1 and Q1 are built on a tiny monolithic silicon chip their base-emitter voltage characteristics will be quite similar. Therefore, the emitter current of Q1 will, for all practical purposes, be equal to the diode current. This current established in Q1 will be shared in some manner by Q2 and Q3 depending upon the voltages at V₁ and V₃. If V₁ is at least 114 mV greater than V2, Q3 will not conduct and all the current will flow through Q2 and Q1. Under this condition, the gain of the entire module is at a minimum. However, if V1 is less than V3 by 114 mV or more, all the current will flow through Q3 providing maximum circuit gain. This characteristic should give a hint as to one of the several possible applications of a voltage applied to the base of Q2, i.e., it's a very good point to apply AGC voltage.

Now, let's consider signal operating conditions, the incoming signal is applied to the base of Q1 and the output signal is taken from the collector of Q3. Thus, Q1

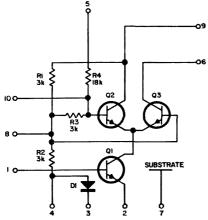

Fig. 2. Schematic diagram and photograph of the Motorola MC 1550. Terminal numbers refer to leads on TO-5 type package.

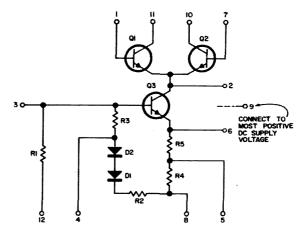

Fig. 3. Schematic diagram of the RCA CA 3005 integrated circuit rf amplifier.

and Q3 are functioning as a common-emitter common-base pair which is better known as a cascode configuration. This configuration has a very distinct advantage because it considerably reduces the internal feedback as compared to a single transistor. The fact that the internal feedback is extremely low means that these circuits (the MC 1550 and CA 3005) are very stable, and you won't have to concern yourself with neutralizing.

Another performance advantage is the AGC capability of these integrated circuit devices as compared to a single transistor. The application of an AGC voltage to Q2 has negligible effect on the operation of Q1, hence, the input characteristics of Q1 remain constant. Thus, there is no detuning of the tuned input circuit with changes in the AGC voltage.

Both the RCA and Motorola circuits can be operated as a differential amplifier with minor external modifications in the wiring. Some of the options of using the cascode configuration or the differential configuration will be covered later.

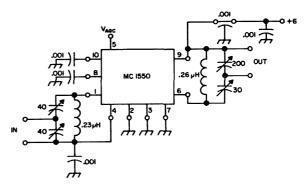

Fig. 4. Typical 50-60 MHz tuned amplifier. Gain is 30 dB with 0 volts AGC and bandwidth is 5 MHz.

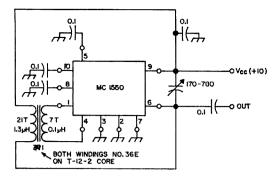

Fig. 5. VFO covering 5 to 10 MHz.

A diagram of the die for the Motorola MC 1550 is shown in Fig. 2. The tiny silicon chip contains the three transistors, four resistors and the diode. Resistors R₁ and R 2 bias D₁, and also provide a base voltage for Q3. The other resistors R₃ and R₄ broaden the AGC voltage range from the previously mentioned 114 mV to about 0.86 volts to reduce susceptibility to noise interference.

The schematic diagram for the RCA CA

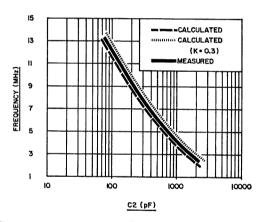

Fig. 6. Frequency vs. Cv.

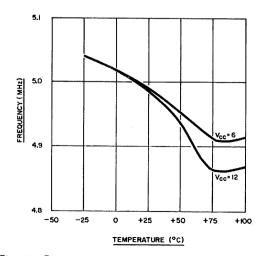

Fig. 7. Frequency vs. temperature.

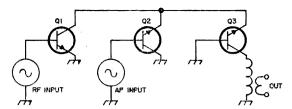

Fig. 8. Simplified model of the MC 1550 used as an rf modulator.

3005 circuit is shown in Fig. 3. While the basic transistor configuration is the same, the biasing arrangement is different and the CA 3005 does not contain the AGC improvement resistors. However, RCA recommends other methods for applying AGC.

Applications

Rf amplifier

Now let's see how these two devices can be applied by the home experimenter. Motorola has built a 60 MHz amplifier using the MC 1550 as shown in Fig. 4. According to Motorola data this amplifier has a gain of 30 dB and a bandwidth of 0.5 MHz. For initial experimentation, adjustment of the input and output trimmers (C₁, C₂, C₃ and C₄) should easily move this amplifier to six meters.

Another Motorola circuit employing the MC 1550 is a VFO covering 5 to 10 MHz. This circuit is shown in Figure 5. Data illustrating the performance of this oscillator is given in Fig. 6 and 7.

The excellent AGC characteristics discussed earlier, makes the MC 1550 very useful as an amplitude modulator. A simplified diagram of a typical low power modulator is shown in Fig. 8. By injecting an audio signal to the base of Q2 and an RF signal at the base of Q1, the rf will be amplified by Q3 as a function of the audio input. Remember earlier when it was discussed how the gain of Q3 varied from

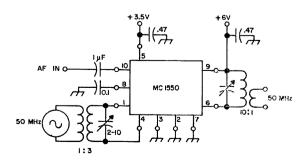

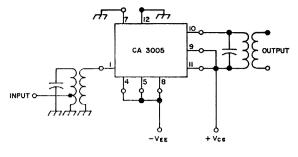

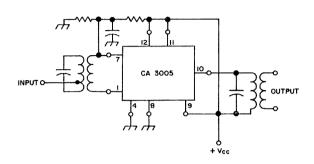

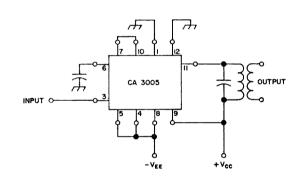

Fig. 9. Low power modulator circuit for 50 MHz.

±3V	22.0	15.0	

Fig. 11. Typical power gain performance of a cascade configuration at various supply voltages.

minimum to maximum with the bias voltage applied to Q2? This circuit yields excellent modulation characteristics with about 90% modulation, both up and down, easily achieved with very low distortion.

A 50 MHz modulator is shown in Fig. 9. This typical circuit should spark ideas for other modulation applications, for example, the previously described oscillator or oscillators at other frequencies could easily be modulated to provide a signal generator or even a low-low power transmitter.

The CA 3005

Now let's take a look at some of the circuits RCA proposes for their versatile CA 3005 integrated circuit.

The CA 3005 can be operated at various levels of supply voltage from 3 to 9 volts and from single or dual dc power sources. Fig. 10 shows the various methods of connecting supply voltages for both the differential and cascode amplifier configuration and for single and dual supplies. Fewer

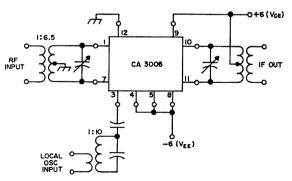

Fig. 12. Typical circuit diagram using the CA 3005 as a mixer.

(D)

external components are needed with the dual supply. To clarify what is meant by a dual supply, take the case of operation from 9 volts. Two nine volts batteries are needed, one for the positive supply Vcc, the other for the negative supply Vee. The other terminal of both batteries is grounded. Notice that when only one supply is used, an external voltage divider and by-pass capacitor is needed for the CA 3005. The MC 1550 has this voltage divider built in the circuit.

The circuits in Fig. 11 illustrate what you can expect from the CA 3005 operating as an rf or if amplifier at 30 MHz and 100 MHz from several supply voltages. Of course, several of these integrated amplifiers can be cascaded to provide additional gain. However, the CA 3004 which has emitter resistors that provide increased signal handling capabilities is recommended in place of the CA 3005 when several stages of if amplification are needed.

Mixer applications

The CA 3005 integrated circuit can also be used as a mixer converter, low power modulator and as a product detector. A typical example of a mixer application is shown in Fig. 12. The local oscillator signal is applied to the base of Q3 and the rf signal is applied either single-ended or double ended to the bases of transistors Q1 and Q2. A mixer-oscillator combination, which could be considered as a complete front-end on a single chip, is shown in Fig. 13.

Using digital circuits in rf applications

The Fairchild μ L 914, which is a dual gate logic circuit, is of particular interest for *rf-if* circuitry. This epoxy device costs

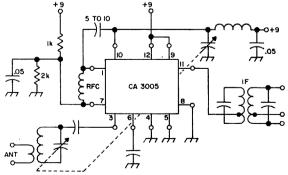

Fig. 13. CA 3005 can function as a complete front end. Part of the circuit acts as a mixer and the other parts as a local oscillator.

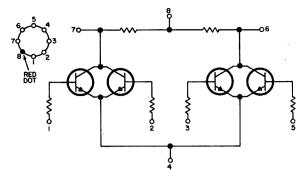

Fig. 14. Schematic diagram of the Fairchild μ L 914 dual gate logic integrated circuit.

only 80 cents and prices are still going down. For this meager sum, you receive the equivalent of four transistor and six resistors. However, for the rf-if applications, you can only use two of the transistors. The complete schematic for the µL 914 is shown in Fig. 14. The 914 can be used at frequencies up to about 20 MHz. At 10 MHz the gain is about 30 dB falling off at frequencies above 10 MHz. Note in the typical circuit shown in Fig. 14 that AGC can be applied giving excellent gain control. Another point to note, also, is that the 914 can handle inputs of about 150 mV or less. Greater signal voltages will cause limiting, hence, the 914 also makes an excellent FM-if limiter.

With this broad introduction to the Motorola MC 1550, the RCA CA 3005 and the Fairchild μ L 914, integrated circuits and the typical application examples, I am sure that many of you will soon be plugging them into sockets. And, before long, there will be construction articles for converters, receivers and even QRP transmitters

. . .Thorpe

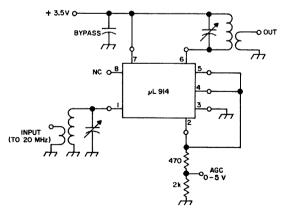

Fig. 15. Fairchild μ L 914 shown in a typical rf-if circuit. Input signals up to 20 MHz and levels up to 150 mV can be handled by this device.

Using Low Cost FET's on Six

The new Texas Instruments TIM12 field effect transistor is excellent for 50 MHz use, yet costs only \$1 in small quantity.

Field effect transistors (FET) seem to be the answer to converter design for the 50 MHz amateur band. The cross-modulation problems common with ordinary transistors and even with tubes are no longer a real headache when using these new transistors. Ordinary transistors are subject to overload and cross-modulation with more than about 20 millivolts input which means that local stations can ride in on weaker signals anywhere in the amateur band. An rf stage ahead of the mixer even with tubes (less overload characteristics) will usually amplify a local station 100 KHz or so away from the desired signal enough to crossmodulate it in the mixer stage. FET types of transistors as mixers have extremely good characteristics for reducing cross-modulation and will even permit the use of an rf amplifier in most locations. Ordinary transistors and even some tube mixer types will often overload enough with an rf stage circuit to make them useless in some locations.

The FET units have been expensive for use in the vhf region and often have exhibited poor noise figure values. The writer recently obtained some new FET plastic-cased transistors for approximately one dollar apiece from a Texas Instrument distributor. These were TIM12 units which have very low NF and good gain values at 50 MHz. A circuit of a good 50-MHz converter is shown in Fig. 1 and illustrated in the photographs. The converter was built on a scrap piece of copper-plated board

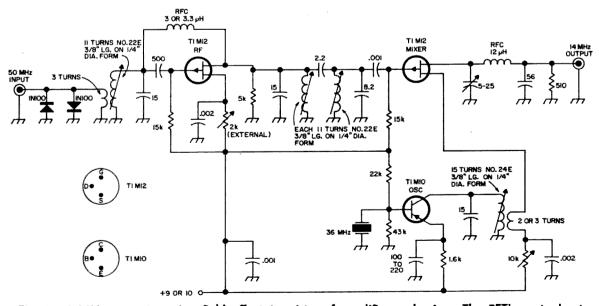

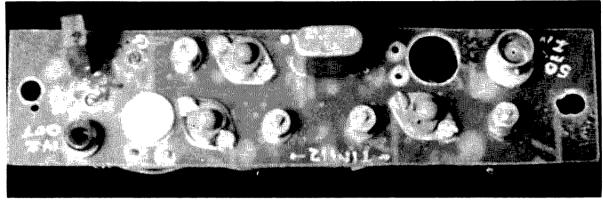

Fig. 1. 50 MHz converter using field effect transistor of amplifier and mixer. The FET's cost about \$1 each. This converter has a noise figure of around 2 dB and great resistance to cross-modulation.

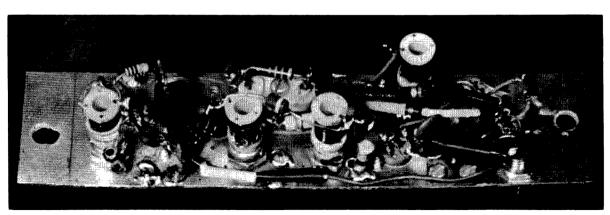

Top view of W6AJF's six meter FET converter. The extra hole by the BNC input jack was used for neutralizing trimmer that proved unnecessary.

1½ x 6 inches for mounting into a 6 inch wide aluminum chassis. The noise figure measurement between 50 and 52 MHz was from 1.5 to 2.5 dB. This is very low and means that in nearly all locations, antenna noise pick-up will completely override the receiver noise.

The cross-modulation capability was checked by connecting two signal generators to the input jack. One signal generator was connected to the converter input thru a 10 dB pad and, with no modulation, was set to give an S5 or S6 signal reading in the if receiver when the whole system was tuned to this signal frequency. Then another tone modulated signal generator was turned on at about 1 MHz off frequency (connected directly to the converter) and its output attenuator adjusted until some over-riding tone modulation was heard on the cw signal generator. It took more tone signal than could be obtained thru the attenuator which was supposed to have 100,000 microvolts maximum output. The "one volt" output jack produced appreciable cross modulation. It was estimated

that it took about 1/4 volt to produce objectionable cross-modulation. It was necessary to have a large resistor pad between the converter and the if receiver, and to have the two test signals separated far enough apart so the cross modulation problems in the if receiver were negligible. It is surprising how poor some homemade and some commercial radio receivers are for cross modulation in the 14 MHz region. It would seem that FET transistors should be used in all 14 to 18 MHz and 5 or 2 MHz if and mixer stages right up to the main sharp mechanical or crystal filter in the if section. A 20 dB pad on the if receiver input helped to reduce these effects while trying to check the converter only. The added pad or attenuator was only a stopgap cure since the real cure is to use a better designed if receiver.

Surprisingly, the IN100 back-to-back diodes in the receiver input were not trouble-some in these cross-modulation tests. These diodes are standard on all my converter inputs in order to provide some transistor protection from moderately high powered

Bottom view of the low noise, low cross-modulation FET converter. The copper shield is across the rf amplifier socket. The solenoid rf choke at the other end is part of the pi network output circuit.

transmitters at this station. The 1N100 diodes have a low capacitance, reasonably high back resistance and quite low forward resistance and are low cost types. Connected across the coax input jack, the diode loss is very low and it does provide some added protection against destructive surge voltages from the antenna system or switching relay.

The converter rf stage required some neutralization by means of a 3 or 3.3 microhenry rf choke connected between the input and output tuned circuits. This resonates roughly at 50 MHz with the gate to drain capacitance of a TIM12 which is typically about 3 pF. Even with this amount of inductive neutralization it was necessary to load the tuned input circuit down to quite a bit less than 1000 ohms by means of the antenna link of three turns. The FET has high input and output impedance and a 5000 ohm resistor across the output tuned circuit was also needed. A variable source resistor of 2000 ohms was mounted external to the converter to permit easy rf gain adjustment.

The FET mixer stage in this unit has gate signal input and source oscillator injection. A small Trimpot, 0 to 10,000 ohms, provides bias for the mixer stage. This pot and the oscillator pick-up link of 2 to 3 turns were adjusted to provide minimum cross-modulation effects. Actually a $2-k\Omega$ or $3-k\Omega$ fixed resistor would be quite satisfactory for this type of transistor and oscillator injection voltage. The latter is greater than with ordinary transistor mixers, but should be a little less than that which gives

maximum mixer gain. At the maximum gain value, the cross-modulation effects are worse. The mixer output circuit is a pi coupling network tuned to about 15 MHz. The dc path resistor across the output jack can be made much lower in value if a wider if frequency response is needed. The value will be somewhere between 50 and 500 ohms for most if receivers. If the latter actually looks like 50 to 70 ohms, the dc shunt resistor can be of a higher value.

The 36 MHz crystal oscillator uses a TIM10 or any other VHF transistor which will produce strong 36 MHz output with one or two milliamperes of collector current. The emitter bypass capacitor produces regeneration and its value will usually range between 100 pF and 220 or even more for most types of PNP transistors. The FET TIM12 units are P-channel which is similar to PNP transistors for battery supply polarity. Some FET units are N-channel which require the same supply voltage polarity as NPN transistors. The TIM12 has an odd base arrangement of leads (see Fig.1) as compared to ordinary transistors. This can cause some confusion in wiring up the transistor sockets and requires a little care in checking over the circuit wiring before fixing up the converter.

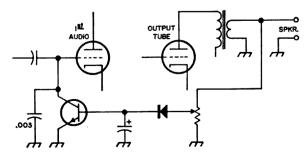

As a final comment, this converter showed a 25 to 30 dB improvement in cross-modulation as compared to several other 50 MHz converters using ordinary vhf transistors of several types. It also had a better NF than the other converters. The spurious signal responses were less due to the FET mixer.

. . . W6AJF

Simple Audio-Derived AGC

I don't claim originality for the basic idea here. Obtaining AGC voltage from the audio output is as old as audio output. The schematic tells most of the story; it will help others equip their receivers with effective AGC from junk box parts with only one internal connection. The transistor is not critical, although it must be NPN silicon (high collector to emitter resistance with no signal or small signal). I've tried about fifteen, from 2N33, 497, 2195 to 2N????, and they all work. The variable resistor can be anything over 50 ohms; I used 10 kilohms, and an audio taper is better than linear. Diode—any germanium: 1N34, 1N277, etc. Base capacitor will de-

pend on each operator's taste on delay time. $40~\mu F$ works fine. The circuit provides fast attack and on three receivers has given an average of 30 dB compression with the pot at maximum. Receiver volume control should be set for loudness with minimum signal and maximum is set with the AGC pot. . . . N. H. Chamion W6BGQ

Low Cross-Modulation at 144 MHz

The biggest culprit in most cases of cross-modulation is the mixer. In the converter described in this article, W6AJF uses a low cost FET for the mixer, which gives low cross-modulation, and a low cost VHF transistor for the rf stage, for low noise figure.

The 144 MHz band sometimes has enough nearby stations to cause trouble in receiving on this band. Very strong local or line-ofsight transmitters can overload the usual transistor converter and ride in on top of the desired signals even though far enough removed in frequency so the selectivity of the main if system should eliminate this effect. Usually the trouble can be traced to the converter transistor mixer stage since perhaps 20 millivolts of signal will produce cross-modulation on top of the desired signal. The answer in most cases is to use an FET type as the mixer since it takes ten to twenty times as much input to show cross modulation. FET devices are usually better than nearly any type of tube mixer at vhf.

FET (field effect transistors) have been very expensive in the past but now some are in the one dollar class such as the TIM12, a plastic-cased transistor. It works very well as a mixer at 144 MHz but is not too good as an rf stage. The converter shown in the photographs and in the circuit diagram was originally built with two FET TIM12's in it, one as the rf stage and the other as the mixer. The noise figure measured about 5 dB which isn't bad for average local station reception but isn't good enough for 144 MHz dx signal reception. The TIM12 is a p-channel germanium FET unit sold by Texas Instrument distributors for \$1.07 at the time the writer

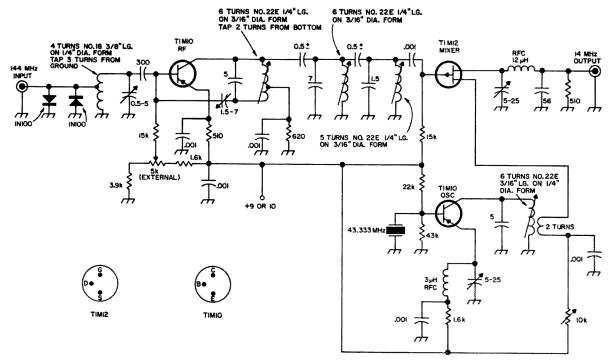

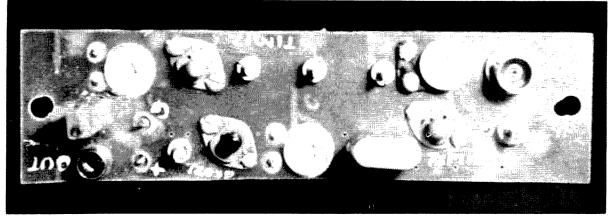

Fig. 1. Schematic of W6AJF's low cost, low noise, low cross-modulation, two meter converter. Note that only the mixer uses an FET; the mixer is responsible for most cross-modulation.

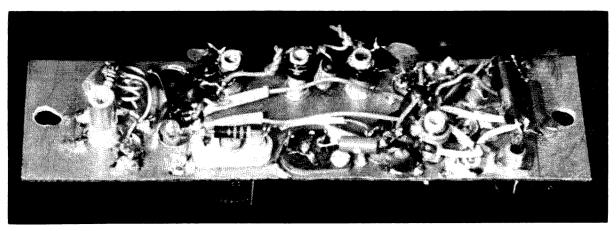

Top view of the converter described in this article. It's built on a $1\frac{1}{2}$ " x 6" piece of copper-clad board. The copper is on the underside.

obtained a few. The rf gain and NF varied greatly at 144 MHz though these same units gave excellent results at 50 MHz in an rf stage. Apparently at 144 MHz the TIS34 FET (at 4 times the price) would be needed and it is an N-channel silicon transistor requiring a change in battery supply polarity.

It was decided to use a neutralized TIM10 vhf transistor (approximately 50 cents) in the rf stage, and oscillator, and the lowprived FET as the mixer. The resulting circuit is shown in Fig. 1. The NF measured at 2 to 3 dB which is fine for dx reception. Two 144 MHz signal generators were connected together thru a 10 dB pad (50 ohms) and the tone modulated generator also tied into the converter directly. The unmodulated signal generator was adjusted to 145 MHz and its output attenuator set to give an S-6 signal into the converter and if system. The tone modulated signal generator was then set to 144 or 146 MHz and its output increased until some tone could be heard riding in on top of the "cw" signal at 145 MHz. With maximum rf stage gain and maximum mixer gain, it took about 25,000 microvolts to cross modulate the S-6 desired "cw" signal. By increasing the mixer source variable resistor to 2-kΩ ro 3-kΩ the "tone" signal had to be increased to 50,000 μ V or 50 millivolts. If a local signal is greater than that, some benefit can be obtained by using forward gain control on the rf stage. For extreme cases of cross modulation, a TIS34 N-channel FET stage (neutralized) would be desirable in place of the PNP ordinary TIM10 transistor.

Just changing the mixer stage from a TIM10 or other types of vhf transistors, to a FET mixer such as a TIM12, improves the cross modulation characteristic by at least 20 dB. The 50 MHz converter shown in the May '66 issue of 73 Magazine and the 144 MHz converter in the June '66 issue were modified to use the FET mixers only. Type TIM12 FET units look like the TIM10 ordinary units but have a different basing

Bottom view of the converter. The "gimmick" capacitors between the three tuned circuits are about 1/2 pF apiece. They should be adjusted for best coverage of 144 to 148 MHz.

arrangement as shown in the new circuit diagram. The 10-KΩ variable source resistor was not used in these modifications. Only the fixed 3.3 kΩ former emitter resistor was used in the source lead with an .001 μF bypass and two turn pick-up link to the oscillator coil. The gate is a fairly high impedance even at 144 MHz, so should be connected to the top of the tuned circuit instead of thru a one turn link as with an ordinary transistor mixer. Note that the FET unit only requires one resistor to the plus supply voltage rather than the voltage divider normally used with ordinary transistors.

The overtone crystal oscillator uses a low-O emitter circuit tuned above the fundamental frequency of the crystal (about 14½) MHz). This emitter circuit has to be tuned below the overtone frequency of 431/3 MHz. Too low a LC ratio, at perhaps 25 or 30 MHz, may not give enough regeneration at the 130 MHz collector frequency with some transistors to give good output power at 130 MHz. The TIXM05 crystal oscillator functions very well with a 5-25 pF adjustable ceramic capacitor and a 3 µH rfc. The TIM10 is a little marginal with these values and perhaps a 4 µH rfc and smaller capacitor might be better. The proper values are those which provide a very weak 431/3 MHz oscillation at the overtone crystal frequency and doubling or tripling power to the desired output frequency in the collector to emitter system. Low rf power oscillation at 431/3 MHz should mean low rf crystal current with attendant high frequency stability. However, the transistor has to oscillate at 431/3 MHz and efficiently triple to 130 MHz. Regeneration at 130 MHz helps increase the 130 MHz power output without running much rf at 431/3. These oscillators, where one does the work of two, can be made more stable in frequency but do require some experimenting to get them to work with each change in transistor type. The writer has never had any difficulty with their use over long periods of time, but does sometimes have to work on a particular converter to get it into reliable oscillation the first time it is tested. The 3 microhenry coil can be wound from coil table or calculator data. or it can be a commercially made small encapsuled rf choke. If one doesn't work, don't be afraid to try another one as the tolerance on some rf chokes is awfully wide. Actually, a ferrite-cored rf choke of 3 or 4 micorhenrys will have a higher Q than "air wound" varieties and produce oscillation more easily. The unloaded Q of this coil should be at least 15, with higher values being desirable. The transistor should be a type with good vhf gain and a cut-off frequency of at least six times the overtone crystal frequency, and a few times the harmonic frequency desired. Like most harmonic generators, the second harmonic is upwards of twice the value as for the third harmonic. The fourth harmonic is usually too low in amplitude to be used in vhf converters.

The 30P1 Linear Amplifier -A Peasant's 30L1

The commercial trend toward smaller and lighter equipment has been only slightly followed by the home builder. The reasons are many. The newer smaller components are expensive, difficult to obtain in some cases, and of course one has to make use of all the goodies present in the junk box, and of the surplus bargains.

The amplifier described here was planned to be as small as possible, yet provide kW, or near kW power. It offers nothing new in circuitry, being the standard 811A rig already described many times in all the amateur publications¹. The only thing different is the packaging. It proves that the proper selection of components, layout planning, and the use of the BIG parts press will result in a smaller piece of equipment of comparable power than usually comes out of the home workshop. All without requiring an elaborate machine shop and using all readily available parts.

The whole thing is squinched into a Bud SB-2142 Shadow Box cabinet, measuring 17 x 11 x 9½ inches, and weighs 57 pounds. Squinched—Lowenbrau inspired contraction of squeeze and pinch). While few of the components are of the junk box variety, all of them are readily available and will present no problem. The total investment on my part was \$80, but this was greatly reduced since the pwwer transformer was on hand. If a similar transformer is available, the amplifier can be duplicated for roughly the same amount.

An explanation of the name is in order. Other than being a take-off on the well known amplifiers, it goes back to my Greenville, S. C. days. When I graduated to a 4-1000A, I proclaimed loud and often to my 811A operating friends that 'any ole peasant can run 811's. Hence the '30 Peasant 1'.

1. For instance, March 1962, page 33.

The circuit: As already stated, nothing new or unusual is claimed for the circuit, and space will not be wasted to show a schematic that can be found in back issues. It is a standard grounded grid, cathode driven pi-net output configuration. The power supply shown provides 1520 Vdc, while 4.5 volts negative bias is furnished by a filament transformer supply. The Barker and Williamson 851 pi-net tank is used in the output circuit, with added contacts being used to switch in added capacitance for loading on 75/80 meters only. Metering is provided in the grid and cathode circuits, as well as an rf voltmeter which provides relative power output indication.

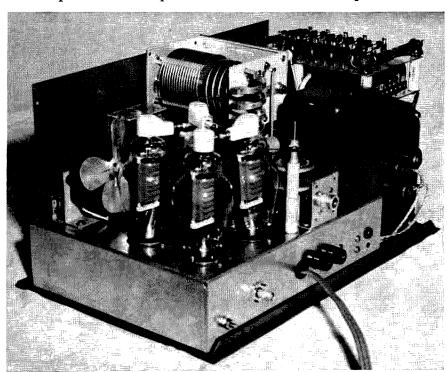

The power supply: As already mentioned, the power supply delivers 1520 volts with the transformer used. It is a full wave circuit, using nine 750 mA 600 piv silicon rectifiers in each leg. The particular rectifiers used here were obtained from Barry Radio in New York, and sold for 36c. There are many bargain counter type rectifiers on the market today, though many turn out to be the bargains they appear. These silicons from Barry have been used in a number of my projects and I recommend them unconditionally. Negative lead filtering is used, mainly to reduce the required voltage, insulation and physical size of the choke. Four 100 µF/525 volt paper filter capacitors are used in series. The resulting 25 µF at 2100 working volts maintain a fairly constant output voltage. These capacitors are

shunted with 100 $K\Omega$ 2 watt resistors to equalize the voltage drop across each individual unit.

Fuses are used in the primary of the high voltage transformer as well as in the B+ line itself. The latter is a Buss High Voltage HVB type, rated at ½ amp. These particular fuses are manufacturer rated to carry up to 135 per cent load. The ½ amp size used here seems the best choice to protect the particular rectifiers used.

The rectifier and filter assembly is made up of two similar pieces of lucite, supported and separated by 1¼ inch steatite spacers. Right angle brackets hold the entire assembly on top of the power transformer. One-half inch screw-type standoff insulators are mounted on the top piece to support the rectifiers, paralleling resistors, and also the current limiting resistors. The high-voltage fuse holding clips are also mounted on the top piece, toward the back so it can be accessible by removing the back cover of the cabinet.

Construction: A few words now concerning the sheet metal work involved. The Bud cabinet used comes apart in four pieces; top and sides together, front, back, and bottom. This is an ideal setup since components can be mounted directly to the bottom and the rest of the cabinet built up around it. One drawback is the fact that the cabinet is made of steel, and is difficult to work, but the small number of holes required makes this a minor problem. The

Back view of the linear with the power supply in place.

meter hole was cut with a Sears and Roebuck adjustable hole cutter which, with plenty of oil went through with no trouble without burning up the cutter blade.

A hint of the use of such cutters: Remove the ¼ inch pilot drill and replace with a short piece of ¼ inch shaft material. Drill a % inch hole in the panel and install a ¼ inch inside diameter panel bushing for the shaft to ride in. After centering the work carefully, clamp securely to the drill press table and feed slowly. In the case of steel panels, oil should be applied steadily as the cut deepens. Oil is not required while cutting aluminum, although it should be used in the panel bushing at all times. In the latter case. cutting should be stopped periodically to remove the buildup of material that accumulates on the cutter blade, insuring a clean cut.

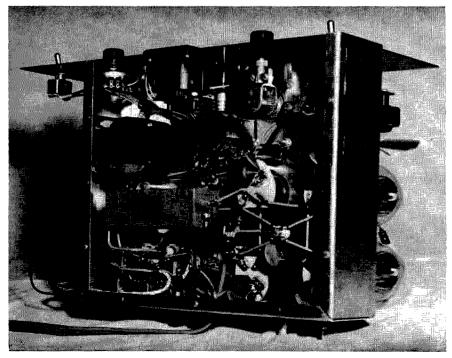

The power transformer is mounted directly to the cabinet bottom using rubber feet on the outside. This provides firm support for the transformer. Rubber feet are also installed on the opposite end of the bottom in the opposite locations used to mount the transformer. The chassis is a Bud AC-418 17 x 12 x 3 inches, cut down to 10 x 12 x 3 inches. The resulting open end is placed against the front panel and secured with threaded right angle brackets.

To provide ventilation, the solid back provided with the cabinet was discarded and replaced with a like-size piece of Reynolds perforated aluminum. Also, three 1-inch holes were punched in the forward edge of the sides, and 'C & G' 1-inch perforated ventilating hole plugs were installed.

Tank coil and plate tuning capacitor are mounted on a bracket made from 3/32 inch aluminum and really serves two purposes. Primarily it supports the coil and capacitor, but it also provides a mount for the bleeder resistors and a heat sink of sorts to help dissipate the heat generated by them.

The B & W coil was modified by the addition of an extra set of contacts to the switch on the back, to switch in a 1000 pF/-1250 volt mica capacitor for loading in the 75/80 meter band. The contacts are installed in the normally blank position, and further modification is required to the detent plate on the front of the coil assembly. This modification consists of drilling a hole for the spring-loaded ball bearing to drop in and hold the shaft in the proper position. A quick look at the coil, switch, and detent plate will readily clear up any vague points. Extra switch contacts can be obtained from Barker & Williamson, Inc. for \$1.00. Don't forget to mention the type of coil.

The plate loading variable capacitor is a broadcast type triple 420 pF unit, also from Barry Radio. It is mounted vertically against the chassis and driven through a National 'RAD' right angle drive. This method of mounting was used to permit a short RF ground path, a short connection to the output side of the pi-net coil, and also because the darn thing was too long to mount any other way. Actually, it is efficient for the

Bottom view of the 811A linear described in the text. This is the rf section; the power supply fits in the space at the left.

reasons mentioned, and helps to maintain a symmetrical front panel.

The ten meter portion of the coil is removed from its original mounting, the ends rebent, and placed as seen in the accompanying photographs. Two Centralab 858S 1000 pF 5 kV capacitors are used for plate coupling and mounted directly on the ten meter coil. Copper strap ½ inch wide is used for all plate circuit connections.

Due to the height of the tubes, the sockets have to be submounted. A 11/2 inch socket punch is used to cut clearance holes for the tube bases, and also for the Millen R-175A plate choke. The Johnson 122-224 sockets used for the 811's are mounted on 11/4 inch spacers. The base provided with the choke is removed and the choke is mounted directly to a 1/8 inch thick phenolic rectangle mounted on the inner tube socket mounting screws. This can be seen in the accompanying bottom view photographs. The B & W FC-15 filament choke is mounted under the chassis on 1 inch standoff insulators to clear the high-voltage line running from a feedthrough insulator close to the edge of the chassis, to the rf choke, and to the choke by-pass capacitor. Also, mounting the filament choke at this height puts its terminals at the same level as the tube connections. resulting in shorter leads.

Suggested changes: Bias. As originally built, the 811's are not cut off during standby periods, and the resulting plate dissipation makes the whole thing run a wee bit on the warm side. I recommend a higher voltage bias supply, with external switching thru the vox circuits, to apply cutoff bias during standby periods, applying operating

bias as drive is applied.

Fan: The fan used does an adequate job, though since building this I have discovered the Rotron muffin fans, and their newer Skipper fans. I used the former, and recommend them for this or any similar applications. They are small, death quiet, and the amount of air they move has to be felt to be believed. They are almost as windy as some 75 meter operators.

The filter/rectifier sandwich should be changed to a triple-decker. The top, or added section, would be a similar size piece of lucite mounted on proper height spacers to clear the components already mounted. This is for safety reasons only as the exposed high-voltage could result in a shocking situation during the initial cover-off smoke test.

Many UHF converters suffer from lack of local injection. W60SA seems to have solved this problem in his converter. Maybe you could use his arrangement.

An Improved Multiplier for UHF

Les Maurer W60\$A 209 Nob Hill Way Los Gatos, Calif.

It seems to the writer that every UHF converter he builds up with the same basic deficiency—marginal crystal current through the mixer diode. This deficiency in turn has always been traced to the same cause—low output from the last tube in the multiplier string.

Maybe this is because I operate my multiplier tubes at their rated input while other builders follow the good old California custom of doubling the manufacturer's recommended plate voltage. Or maybe I am just a careless builder.

After putting up with this nonsense for a couple of years it was decided to grip the bull by the horns and construct a souped up multiplier string. The next question was how to soup it up without turning it into a transmitter. Remembering K1CLL's article on neutralizing receiving type tubes in the August 1965 73, it was decided to try a 6AK5 straight through amplifier at the 3F point in the chain (141 MHz in this case).

The old multiplier string was modified to look like Fig. 1. Following KICLL's advice, the 6AK5 amplifier was first tried without neutralization, and as usual, no luck. Next, we added the neutralizing loop and two twists of hook-up wire for Cn. Got the loop backwards the first time as predicted. Reversed the loop and "Voila" about ½ watt of stable rf energy at 141 MHz. How do

I know it is watt? Well, it lights an NE 52 neon bulb if you touch the tip on the tank coil. Also, be it noted, the light goes out when you pull the crystal out of its socket, which it did not do prior to neutralization.

The writer uses the unit in Fig. 1 to drive a Raytheon 5656 dual tetrode operating as a push-pull tripler to 423 MHz. The 5656 has recently turned up in surplus houses at about \$2.50 and is indeed a nifty UHF low power multiplier or amplifier. It appears to put out about 1/2 watt at 423 when used as a tripler. The writer used the plate lines out of an old APS 13 oscillator, 1/4 wave at 423 MHz and a 4 turn grid coil resonant at 141 MHz and link coupled to the preceding unit (Fig. 1). The output of the 5656 is link coupled through the original APS 13 link to a varactor multiplier in my K6AXN/ W6AIF mixer box which is tuned to 1296 MHz. This produces 350 µA of crystal current in the 1296 MHz mixer diode (1N21C) even when very loosely coupled and with the 5656 running cool (140 volts on plate).

In addition to now having all the mixer current I can use, there is an added bonus, (where did all the birdies go?). Apparently, as a result of inserting the straight through amplifier and the addition of three more tuned circuits followed by a push-pull tripler in place of the old single ended stage; all the birdies which normally wend their way

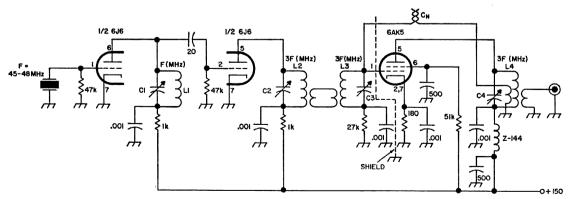

Fig. 1. Low power exciter-local oscillator. Output is in the 140 MHz range for use as local injection in a 1296 MHz converter.

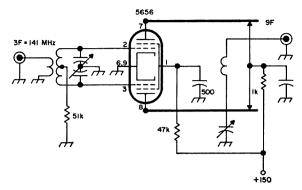

Fig. 2. Tripler from 141 to 423 MHz. This circuit uses the plate lines from the old APS 13.

up the multiplier string were knocked out. This in itself would probably justify the effort.

It appears that commercial designers of military equipment (not ham equipment) feel that the use of push-pull triplers and link coupled straight amplifiers in a local oscillator chain is good practice. I have since discovered that the LO chain in the AN/FRC-34 1800 to 2000 MHz receiver, built by GE, has almost the same arrangement. They went a little overboard on power. The FRC-34 has an 832A where I have the 6AK5* and a 2C39 where I use the 5656. Who needs a transmitter? Just modulate your LO, provided it's in the band.

As a matter of fact, the 6J6-6AK5 unit would make a neat flea power two meter rig. All that is needed is a suitable crystal, like 48.4 MHz for instance, and a 6AK6 modulator driven by a carbon mike.

With regard to tube substitutions, the 12AT7 could be used in place of the 6J6 if desired. I can't think of a substitute for the 6AK5 off hand, but show me the UHF ex-

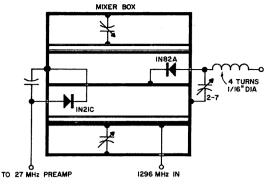

Fig. 3. 1296 MHz converter front end. Input at right is 423 MHz from the tripler in Fig. 2.

perimenter who doesn't have a few in his junk box and I'll send him a couple. The 5656 is a little more of a problem. A pair of 6J4's would also work. These little tubes have turned up in the surplus around here for as little as fifty cents a piece. They are outmoded as receiver amplifiers but still look mighty good as low power frequency multipliers up to at least 450 MHz. Check the Cm in your tube manual. There is the added advantage that if the APS-13 transmitter box is used, the 6J4's would plug into the 7 pin miniature sockets already there with only minor changes in the pin connections.

One final picce of advice with regard to the 1N82A varactor multiplier, I had all kinds of trouble driving these things until I tried the "L" network out of the ARRL VHF Handbook (see Fig. 3). Since that time, no more trouble has been experienced in getting the drive out of the 423 MHz tank and over to the place where it is needed on the ungrounded end of the varactor.

. , . W60SA

Measure Relative Power and Plate Current

A relative power meter on a sideband transmitter or transceiver is quite useful in tuning for maximum output, but at times it is helpful to know the final plate current.

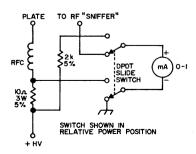

The circuit shown has been used on an HX-20 and has proved quite useful as a check on operating conditions, as well as an indication of power input. With the resistors used and the 0-1 mA meter switched, full scale deflection is approximately 200 mA. Be sure to insulate the meter and switch for full plate voltage.

The desire for a plate current meter arose upon changing the final tube to a

6146-B and increasing the plate voltage to 750 volts in an effort to obtain maximum drive for a linear amplifier.

Only a minimum of time and parts are required to install the above circuit and it is well worth the effort if it saves a final tube from going bad.

. . Carl Pleasant W5MPX

A Broad Band 80 Meter Vertical

Tired of narrow band antennas that have to be retuned when you change from CW to SSB? Here's an antenna that covers the whole 3.5 to 4.0 MHz band without any adjustments.

Being an advocate of DX and contests, most of my operating time is spent on 20, 15 or 10 meters, but there is the odd time that the urge hits me to try 80 and 40, especially during an all-band type of contest. Unfortunately the usual type of array which one finds on 20 meters and higher is in most cases impractical on the low bands because of size and cost. In order to get the necessary low angle of radiation so necessary for DX, the most logical type of antenna to choose is the vertical, but even this becomes a bit formidable when

Fig. 1. Basic configuration of VEITG's broadband 80 meter vertical. The idea is old, but it works well.

one gets down to 3.5 megahertz.

My old reliable antenna for 80 was the familiar inverted V, or drooping dipole, which has served me well in many different places. The same goes for 40, but having finally landed in a fairly permanent QTH it seemed the time had arrived for a more serious effort.

As far as 80 was concerned, the major requirements of the antenna were:

- 1. Simplicity and ease of construction.
- 2. Low cost.
- 3. Low angle of radiation for DX work.
- 4. Broad band of operation to cover both 3.5 CW and 3.7 to 3.8 SSB.
- 5. Coax feed.

Considerable thought was given to the usual ground plane type of array, but considering the heights involved, this was discarded in favour of the vertical quarter wave with radials on the ground. As will be seen, the actual result was quite a departure from the usual single vertical radiator. Fig. 1 shows the complete design of the antenna in its final form. The main support of the antenna is a 50 foot wooden A frame. Six lengths of wire are cut. The longest is 66 feet, and each other wire is one foot less, with the shortest being 61 feet. The upper ends of the wires are well soldered in parallel, and are mounted to the top of the A frame by whatever means is convenient. In my case I used a stainless steel strap which encircled the top of the mast, and to which a large cable clamp was bolted. The wires were then soldered to the clamp.

At a point about two-thirds down the length of the wires, an insulator is fastened, and by using ropes or other suitable strong

lines, the six wires not only act as radiators but also as guy wires. Note from Fig. 2, that the wires are merely looped through the holes in one end of the insulators and then carry on down to the base of the A frame. At this point, all six wires are again soldered together and fastened to the mast by the use of a stand-off insulator. Now when the guy ropes are pulled tight, the antenna becomes a conical shaped multielement vertical. Because each wire is a different length, and each length is resonant at some point in the 80 meter band (1/4 wave) the antenna as a whole is broadly resonant over most of the band. In my own case, I was only interested in operating up to about 3.8, but the antenna performs very well right up to 4.0 MHz.

The vertical structure is really very simple to build, as the wires are actually nothing more than insulated guy wires for the A frame. The construction of the frame will be covered in a moment, but first let's finish the antenna. The only way to really get the most out of the array is to have as good a ground radial system as possible. There is probably only one rule-of-thumb on radials: the more, the better. Being very cost-conscious, I found the cheapest source of copper wire for the radials was the nearest motor-repair shop. There is undoubtedly such a shop somewhere near every small town in the country, and of course in a city there will be quite a few. You'll find that in most cases you can get old motor coils either free or for a nominal chargeusually based on the junk value of copper per pound. Another excellent source of such wire is an old line transformer or distribution transformer which your local utility may have removed from service. In a farming area, electric fence wire is fine.

The method of laying the wire must be

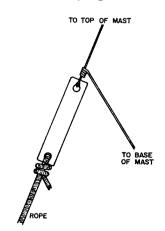

Fig. 2. Details of the insulators in the antenna.

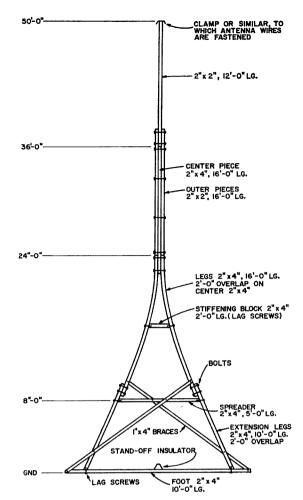

Fig. 3. Construction of the 50 ft. wooden mast for the vertical. Don't use a metal mast.

determined by your own geography. In grassland or sod, it's easy to cut a slit in the sod and tamp the wire down out of sight. In rocky terrain, it may be necessary to either dig out a path or merely lay the wire on the ground and cover it with some loose dirt or sand. The wires need not be in a straight line; almost any configuration will work.

You will find that laying the radials is the biggest and hardest part of the array, but doing a good job here will really pay off on the air.

In the case of my own antenna, I used RG-8 coax, 52 ohm, which matched the thing very well without the use of any other devices. The SWR over the band was about 1.3 to 1.8, which is certainly good enough. Undoubtedly the match could be made more perfect at some frequencies, or a tuning unit could be used to adjust the antenna as one moved across the band. However, the best feature of the antenna as it stands is one's ability to move around the band at will, and without any extra tuning en-

cumbrance.

Making note of the fact that the antenna is also a half-wave high at 40 meters, I have plans to include a tuning unit mounted right at the base of the mast and remotely controlled from the shack. However, this has not yet evolved past the paper stage.

In actual use on the air, the antenna performs as well as the inverted V on short haul contacts, and does very well on DX. Best DX (considering their rarity) has been ZD7 and VS9, but very good reports have been received from Europe, South America, parts of Africa, etc. It is especially nice in a contest to be able to dash hither and yon over the band without constantly grabbing for the plate tank controls!

Fig. 3 shows the construction of the A frame, which is very straight-forward. This is actually an A frame which I have used not only for this antenna, but also to support at times a 40 meter ground plane, inverted v's, one end of dipoles, etc. so its use as a general purpose support is very extensive.

The main points to consider are the ultimate height, and the weight which will be supported. In this area of high winds, ice, sleet, etc. I used the best quality 2 x 4 lumber I could find, and used a liberal coating of wood primer and two coats of exterior house paint. Since the longest lumber I could find was 16 feet, I used extension pieces on the bottom. At the top, I used two lengths of 2 x 2 to both steady

the upper piece of 2 x 4 and also to act as a bracket into which the top section of 2 x 2 was inserted. Since the radiators are acting as guys fastened right at the top, the 2 x 2 is plenty strong enough. Depending upon your local weather conditions, you may or may not require the use of a second set of guys about half way up the tower.

When the A frame is laid out for raising, the wide base will make it an easy task for three people. In fact, if you can secure your guys at right angles and have the use of a small block and tackle, with a tree or similar anchor, you can raise the mast all by yourself.

Because of slight flexing and "working" that takes place in a high wind, I would suggest using only bolts in the mast; nails have a habit of working out at the most unlikely and least desirable times. The guy ropes need not be expensive; I use synthetic cord used to make deep-sea fishing nets, and it works very well.

As a last comment, I hung a 40 meter inverted V right at the top of the mast, and found that this upset the SWR considerably on the vertical, pushing it up to about 2.5 all over the band. This can be taken out by a little tuning at the base, but is probably best avoided by simply not hanging anything else on top. After all you have gone to the trouble of making a pretty good antenna so why spoil it?

. . . VE1TG

Temporary Knobs and Tuning Tools

When working with gear have you ever come across a control you couldn't adjust? It may be inaccessible (as inside an *if* can), or odd shaped, or both. Tools fitting some of these shafts aren't even in the catalogue let alone on your workbench. Fortunately there is a quick, cheap, easy solution to the problem—the ubiquitous ballpoint pen.

Here's the trick. Take the plastic outer barrel of the (presumably) empty ballpoint and remove any metal molded to it. This can be done with a match or a cigarette lighter used as a cutting torch. In the same way melt the barrel till the end is almost the same size as the shaft to be turned. Do this so the barrel will still fit into the space available. Now *slowly* heat the end until the plastic is just softened. Quickly

push over the shaft and let it cool. You will have no trouble removing the pen in a few seconds after it has hardened completely. If done carefully, this process can be repeated several times until a good fit is obtained.

You now have an insulated tool of surprising durability. I have used the same pen barrel to tune a T23/ARC5 for five years. Another one has turned the motheaten splined tuning shaft of a Q-5'er all around the passband of my receiver since Christmas. I suppose as it wears out I'll just reheat it until the cost of matches approaches that of a surplus knob, or vice versa.

You can squeeze even more out of this. A tapered barrel can be treated on each end to make a combination tool. Other applications are limited only by ballpoint sizes, and probably not even by that, using the amateur's last resort . . . ingenuity.

. . . Thomas Kuffel KOYPB

A Reliable Directional Coupler and VSWR Bridge for VHF-UHF Use

The average VSWR bridge isn't very satisfactory in the VHF or UHF range. This article describes an easily reproducible directional coupler that can be trusted even at 1300 MHz.

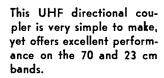

The aerospace industry has fostered the development of many new components and materials. Hams, being the kind of people they are, are quick to see practical applications for these materials that never occur to design engineers. I have often heard the criticism that it is impractical to publish articles or design ham gear with these new or expensive materials, because most OM's don't have access to them. Yet I've often been dismayed when I learn of an application for a piece of surplus equipment after it is no longer available. For this reason I feel that we should publish any application that is practical regardless of how immediately it can be used. Sooner or later, the material will show up on the surplus market and then we'll know what use can be made of it.

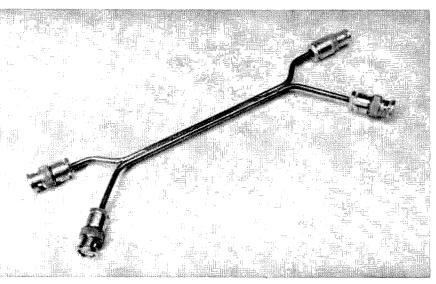

Reliable test equipment for the VHF-UHF bands is difficult to come by on a low budget. The literature is full of "relative" measuring devices but few pieces of homebrew gear are engineered for repeatable performance. Several directional couplers have been built according to the descrip-

tion in this article and each has measured to within ±.5 dB of the designed value. This is due in part to the mechanical rigidity and close tolerance of RG-141 "coaxitube." No special tools are required outside of a cheap pair of vernier calipers. The tools used to make the original coupler were an Xacto knife, file, soldering gun, vernier calipers and a vise. Don't let the calipers scare you. If you're not after a closely calibrated device they may be omitted.

The design goal was a directional coupler with about 30 dB directivity in the passband with a low insertion loss. Each milliwatt measured at the coupling arm equals one watt through the main line. Such a device is the heart of a good quality VSWR Bridge. The measured values were 30.3 dB coupling and 38 dB directivity at 432 MHz. Data presented in the graph was taken using HP608C and 614A signal generators and a General Microwave R. F. Power Meter. The measured insertion loss was 0.2 dB.

Resolution of the smallest possible VSWR is limited by directivity. Few of the handbook VSWR bridges or the low cost type

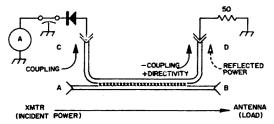

Fig. 1. A typical directional coupler. This device is the heart of a VSWR bridge, and can also be used for many other applications.

attractive to the CB trade achieve as much as 20 dB directivity. Thus the minimum discernable VSWR is approximately 1.7:1. With 38 dB directivity, 1.02:1 VSWR's can be accurately measured.

Directivity may be defined as the isolation of arm D from arm A, over and above the coupling as shown in the Fig. 1. Coupling is achieved by removing part of the jacket between adjacent coax conductors. If the input is at arm A, incident power can be sampled 30 dB down at arm C but appears -68 dB at arm D. Reflected power entering arm B is sampled -30 dB at arm D while at arm C it is -68 dB. It stands to reason if the directivity is low, one cannot tell with certainty if he is measuring incident or reflected power. Port D may be used as the dc return for a detector at port C and vice versa.

This device will have its fundamental passband where the length exposed between the two lines is $\lambda/4\sqrt{\epsilon_r}$. It will also have a passboard at (2n-1) $\lambda/4\sqrt{\epsilon_r}$ or at three, five, seven, etc., times the frequency for which it is a quarter wave. Hence a coupler designed at 432 MHz is usable at 1296 MHz.

This coupler has also been used to measure relative power and modulation at 2 meters where its coupling factor for incident

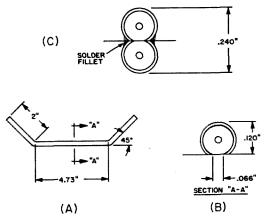

Fig. 2. Details of the construction of the UHF directional coupler.

power is approximately -40 dB but the directivity is poor, hence arm D must be terminated in 50 ohms. It's a real aid for tune up and will give a good indication of increased power with AM modulation right in the r.f. line. RG141 will handle 500 watts of rf up to 2000 MHz.

The formula for determining coupling length is

$$\frac{c}{4 \text{fo } \sqrt{\epsilon_r}} = \frac{\lambda c}{4 \sqrt{\epsilon_r}} \quad \text{or } \frac{300 \times 10^8 \text{ cm}}{4 \times \text{fo } \times \sqrt{2.1} \times 2.54} \quad \frac{\text{cm}}{\text{ln}}$$

$$= \frac{\lambda c \text{ inches}}{4 \sqrt{\epsilon_r}}$$

 $\sqrt{\epsilon_r}$ for Teflon = $\sqrt{2.1}$ = 1.449

From these calculations $\frac{\lambda_{\text{coupling}}}{4}$ at 432

MHz is 4.73 inches. With an Xacto knife cut two pieces of line 8.73 inches long and carefully bend them so that they form the shape shown in Fig. 2A.

Clamp the bent coax into the vise and file away the copper jacket taking care that the filed surface is smooth and flat. A belt or stationery disc sander works well too. A cross section of the filed piece should look like Fig. 2B. Next fit the two pieces together so that a cross section would look like a figure 8 and secure in a vise. Heat with a soldering gun only. Do not use a torch. Avoid excessive heating. Flow solder between the two lines as shown in Fig. 2C. The "arms" can now be bent into any convenient configuration provided enough allowance is made at the ends for connector assembly. A good rule to follow is a minimum bend radius of half an inch although a quarter inch radius is permissible. The arms should be approximately two inches

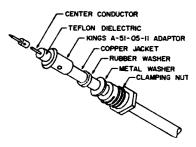

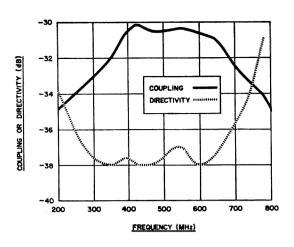

Fig. 3. Use of Kings A-51-05-11 adapter for using GR-141 with standard BNC connectors.

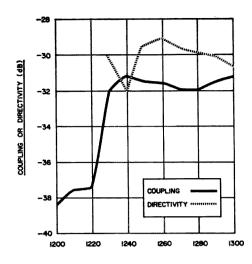

Fig. 4. Coupling and directivity for a directional coupler similar to the one discussed in the text. This device used a coupling wavelength of 4.635 inches rather than the 4.73 inches specified in the text. The only effect of the longer wavelength is to center the curves on 432MHz instead of about 500 MHz.

RG 141 has the same cross section as RG 58/U without the vinyl jacket therefore any connector that will accept RG 58/U can be used on RG 141 provided a sleeve is made up to make a snug fit in the clamping nut. A special adaptor is made by Kings for this purpose and sells for 45 cents. The connector assembly is shown in Fig. 3. Three RG 88E/U and one RG 89C/U connectors were used on the coupler shown in the photo.

Fig. 4 gives the measured directivity and coupling for this type of directional coupler at both 70 and 23 cm. You can see that performance is quite satisfactory.

Fig. 5 lists a number of applications for a directional coupler. The detectors in the measuring instruments should be suitable for use at 500 or 1300 MHz.

. . WA6SXC

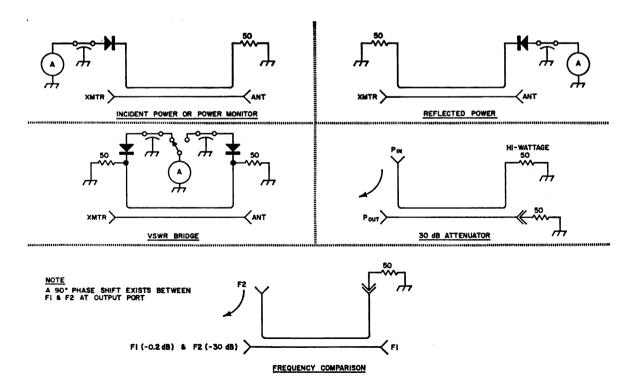

Fig. 5. Applications of the directional coupler described in the text. Unlike most pieces of ham-made test equipment, this one is good at 450 and even 1300 MHz.

Common Base Mixer

73 Magazine

The transistor common-base configuration offers good frequency response, isolation between input and output, very high output impedance, and lots of gain.

Generally used only as an amplifier, it also makes a fine mixer. The parts required are one transistor, an output arrangement, and perhaps a resistor and capacitor. Fig. 1 shows the complete circuit.

L1 and L2 are low impedance links bringing the rf and local oscillator signals. They are in series as shown, not in parallel. No base biasing network is required.

L1, the oscillator input, is wound for about 1 mA of mixer current. R and C are there only so you can measure this current without breaking into the circuit. Then L2

A Solid State Antenna Relay

Mechanical relays and conventional TR switches are unsatisfactory for the ham who wants to enjoy the ultimate in operating. This silicon diode switch offers excellent performance and overcomes the faults of other methods of switching.

A TR switch is basically a single pole single throw switch in series with the receiver, which is controlled by transmitted rf. An antenna relay is a single pole double throw switch controlled by a dc signal. A TR switch has several disadvantages, notably suckout and TVI. A mechanical antenna relay is slow and noisy. A solid state antenna relay has all the good features of both.

The device described here is a diode double throw switch with a dc control lead. It causes no suckout or TVI and does not require tuning. It is fast and silent in operation. It introduces negligible loss on receive.

Theory

The basic switch element in this relay is an

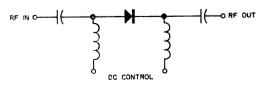

Fig. 1. Basic diode switch element. The diode is silicon. The dc control bias is switched in polarity to open or close the switch.

ordinary silicon rectifier. Fig. 1 shows how de bias and an rf signal may be combined on a diode. If the dc bias is in the reverse direction, the series rf impedance is high (open switch), and if the dc bias is in the forward direction, the rf impedance is low (closed switch). Both of these conditions hold only if certain constraints are met. In the reverse case, the peak rf voltage must not exceed the dc bias or rectification will occur (hence TVI). In the forward case, the rf current must not exceed a value relative to the dc bias which would remove all stored charge in the diode in less than 1/2 cycle; with typical rectifiers this means rf peak = 10 times dc average at 3.5 MHz. Thus a circuit like Fig. 1 is an rf switch which can be controlled by a dc bias.

Fig. 2 shows how four such switches can

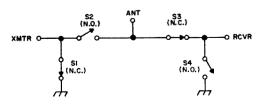

Fig. 2. Four simple diode switches can be combined into an antenna relay.

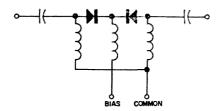

Fig. 3. A simple variation of Fig. 1 avoids charging up a large capacitance when changing from closed to open.

be combined into an antenna relay.

The type of diode used and required bias voltage depend on the open rf voltage and closed rf current in the switch. SI and S3 are subject to high voltages and low currents. 2000 volt 1 watt rectifiers are used with 900 volts of reverse bias and 5 mA of forward bias. S2 must handle high current so five 1 watt diodes in parallel are used, with 1 amp forward bias and 60 volts reverse bias. S4 operates at a low level; a ¼ watt diode is used with 5 mA/60 volts bias.

Fig. 3 shows a variant of Fig. 1 where the bias circuit does not have to charge up a big capacitance when changing from closed to open; this is used for S1, S3 and S4. The leakage from the transmitter during reverse periods may be reduced by use of a toroidal neutralizing transformer.

Band		Leakage from Tx on Revg*	
80	-67 db	-17 dB	2.0 dB

Power capability greater than 1 KW at 80 and 15 meters (tested). Rated 2 KW 3-30 MHz.

Impedance: 50-70 ohm unbalanced

Table I. Performance of the antenna relay.

Operation

Fig. 4 shows the complete rf unit of the relay. As can be seen, it has two dc control inputs A and B. A requires -60 volts at 30 mA on RCV. and +1000 volts on XMIT. B requires -60 volts on RCV. and +5 volt/1 amp on XMIT. Fig. 5 gives a control circuit which supplies these signals.

The operation of this circuit is as follows. On recieve, the control input is grounded, cutting off Q1, whose collector rises toward +20 volts. This cuts off Q2, which goes to

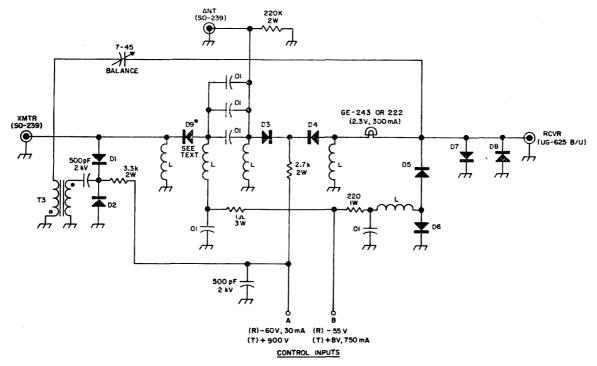

Fig. 4. Rf switch sub-unit. D1 through D4 are 2000 PIV silicon recifiers. D1 and D2 are matched with L in series with D1. D3 and D4 are matched for V_P at 10 mA forward current. D5, D6 are 200 V, 1/4 W rectifiers. D7 and D8 are 1N191, 1N3666 or 1N34A. D9 is five diodes in parallel. See text. Each L is 12.5 feet of number 37 enamelled wire on a 3/8" diameter fiber tube, 3/4" long winding. (60 μ H, 4Ω dc resistance.) T3 is 10 turns of number 25 Formvar bifilar wound on 3/16 ID, 3/8 OD thick Q2 ferramic core.

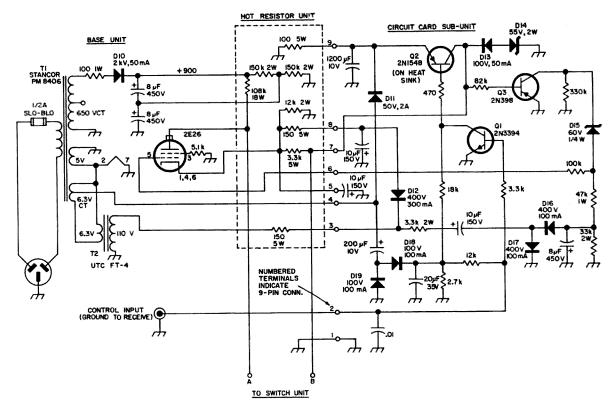

Fig. 5. Power and control for the antenna switch. D10 is a 2000 V, 50 mA rectifier (1N2328). D11 is 50 V, 2 A. D12 is 400 V, 300 mA. D13 55 V, 2 W zener. D15 is 60 V, 1/4 W zener. D16, D17 are 400 V, 100 mA. D18, D19 are 100 V, 100 mA. Q1 is NPN silicon, $H_{\rm FE}$ over 20 and $V_{\rm CEO}$ over 25. Q2 is PNP, $H_{\rm FE}$ over 75 at 1 ampere and $V_{\rm CEO}$ over 75 V in TO-3 case. Q3 is PNP, $V_{\rm CEO}$ over 100 V.

-54 volts clamped by the zener diode. This supplies the B signal. It also saturates Q3, whose collector forward biases, the 2E26, so that A is -60 volts as required.

On transmit, the control input is ungrounded, so Q1 is saturated, as in Q2. Q3 and V1 are cutoff, thus supplying the required A and B signals.

Construction

Construction is not critical, except the rf section should be a subassembly laid out similarly to the schematic and wired with short leads. No heat sinking is required on any of the diodes. The power dissipating resistors should be mounted in the clear atop the chassis. In the prototype, a plugable card held the transistorized drive circuit. The prototype was built on a 5 x 7 x 2 inch chassis and is 6 inches high.

Special components

The diodes used for D9 in the switch unit must be carefully chosen. The authors used 400 PIV 1 amp units similar to IN1763. Each unit could handle 1 amp rf with 100 mA dc bias. (50 watts at 50Ω) Since P =

I2R, 5 diodes in parallel can handle 1 kW. The requirement on the diode is that the stored charge be sufficient to avoid turn-off in a half cycle at 3.5 MHz. This means high efficiency diodes should not be used. Probably most "top-hat" silicon rectifiers will do. To test a given type, place 1 diode at the D9 position and temporarily replace R1 100- Ω 2-W resistor. (This will give about 100 mA de bias.) Load a 3.5 MHz rig up to 75 watts input with a 50Ω dummy load. Connect the relay in the line and close your relay key for a few seconds. If diode gets hot, the type is no good. If not, close the key for 5 minutes; the diode should stay cool to be acceptable.

Operation

In operation, the relay is used like an ordinary mechanical relay. Care must be taken that the control signal is properly sequenced to avoid applying rf when in the receive position. Table 1 shows the loss, isolation and switching times. Needless to say, this unit lends itself to fast highpower break-in with one antenna.

... K2IYC

Video Camera Tubes

There are many ways to generate a video signal. This article discusses them, whether they be well-known or rare.

Many developments have been made in the field of television, the modern camera tube being one of them. The tube, as a unit, has come a long way from the first type which was used in the 1939 World's Fair. This early device was known as the Nipkow Disk, and its operation was quite simple (Fig. 1).

As the wheel rotates, the light, coming through each hole as it passes the object, goes through the wheel and then to the photocell. Since the photoelectric cell is sensitive to changes in light intensity, the varying intensity will cause a voltage to be produced that will vary directly with the light. This varying voltage then becomes the video signal. Each individual hole in the Nipkow Disk contains a lens to properly focus the light to the photocell. A further development of this system that worked along the same lines as the original, with some variations, was known as the Modified Disk (Fig. 2).

An arc light is placed behind the disk and the object is kept in complete darkness. The light coming from the arc lamp is made to pass through the holes in the disk and is then reflected off the object. The light variations are picked up by the sensitive electric eye. These light variations cause a voltage to be developed in the cell. This voltage represents the varying light intensity and is the video signal.

Fly spot scanner

The modern camera tube evolved from these primitive systems, the first type being called the "Fly Spot Scanner". The theory of operation of the Fly Spot Scanner is much the same as that of Nipkow Disk, except that the arc light and the disk are eliminated. This system is still used extensively in the transmission of television, especially in color television. It has also found much use in closeup and still work, as well as the transmission of the television test pattern.

Extensive research in the field of photoelectricity and vacuum tubes brought forth a new development in camera tubes. The

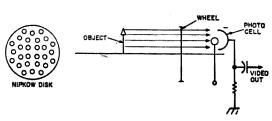

Fig. I. Nipkow disk video pick up.

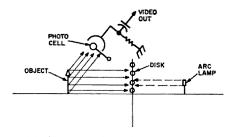

Fig. 2. Modified Nipkow disk.

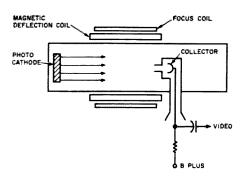

Fig. 3. Image dissector.

idea of the original Nipkow Disk and the photoelectric cell was incorporated into a device called the "Image Dissector" (Fig. 3). This was to be the first camera tube that could reproduce moving images. In order for the tube to properly operate, a photosensitive cathode had to be developed. This element emits electrons when placed under the influence of light. Inductors wound on an iron core, called focusing coils, are placed in certain positions around the outside of the tube. These focusing coils are used to keep the electrons, which are emitted from the cathode, traveling in a straight line or stream. Through the action of the focusing coils, the electrons are deflected in a horizontal direction as well as a vertical direction.

At one instant in time, all the electrons will hit the collector. However, in this process, a great deal of electrons are lost or wasted. In order to compensate for this waste of electrons, an electron multiplier is built into the vacuum tube (Fig. 4). The electron multiplier is a device in which each plate is at a higher potential than the previous one. When the electrons leave one of these plates to go to the next one, their velocity is increased due to the laws of electron ballistics. This action increases the force of the electrons as they strike the light-sensitive cell which results in a theoretical amplification of the original light. A greater potential is then developed at the output of the camera tube, which, in effect, results in a larger video signal to be produced and fed to the video amplifier.

As the state of the art improved, more advanced types of video camera tubes were developed. Among these were the Inconoscope, Orthicon, Image Orthicon, Vidicon, and Monoscope. In the following discussion, each of these video camera tubes is explained.

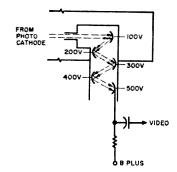

Fig. 4. Electron photomultiplier tube.

Iconoscope

The Iconoscope is shown in Fig. 5. On the mica sheet there are little globules of silicon. Each of these globules is insulated from the other by baking which results in oxidation of the silicon globules. The silver backing, which is coated with cesium, and the mica sheet make up the mosaic.

The scanning beam drives the point on the mosaic that is being struck to approximately 3 volts positive over the value of high voltage. This increase in potential is developed because of the loss of electrons from the mica sheet. These electrons form a cloud that exists close the face of the mosaic. While the beam is driving electrons into the cloud, there is a continual of electrons back on the entire mosaic. In the case of NO PICTURE on the mosaic, the amount of "raining" electrons is equal to the amount of secondary emitted electrons, and the net charge is zero. As a result of the zero net charge on the face of the mosaic, no current flows through output load resistor R1.

When a picture of differences is pro-

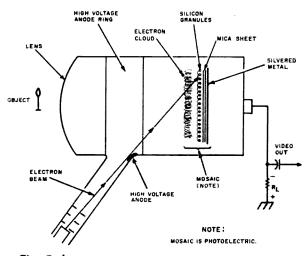

Fig. 5. Iconoscope.

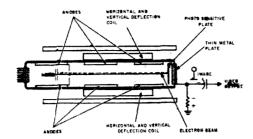

Fig. 6. Orthicon (low velocity beam).

jected on the mosaic, the bright areas under light charge up through the photoemission process and are positive with respect to the dark areas. When the electron beam strikes a bright spot, less secondary electrons are given up. Thus, the amount of "raining" electrons will exceed the amount of secondary electrons and will be equal in value on a dark spot. The greater the brightness, the greater the difference. The unbalance is reflected across the load resistor and is coupled through the capacitor as the changing video signal.

Orthicon

The Orthicon is shown in Fig. 6.

The anodes are metallic rings wrapped around the outside of the tube. The electron beam is emitted from the cathode. Each anode is set at a lower potential than the previous which results in a slowing down of the electron beam. At the time that the electron beam reaches the front metal plate, its velocity is practically zero. The metal plate is thin enough for the image to go through and activate the photosensitive surface to emit electrons.

The image light charges the photocathode positive on the inside. When the electron beam strikes the photocathode at a point, it will cancel the positive charge. The metal plate then discharges through RL, causing a negative voltage with respect to ground to be developed across RL.

The Image Orthicon is shown in Fig. 7.

Image Section. This is the wide end of the tube and is comprised of a piece of glass with a coating of photosensitive material (photocathode). The optical image is formed on the photocathode on the light side while electrons are released from the side facing the target glass. A silver ring, which is kept at a negative potential of -500to -300 volts dc, surrounds the photocathode. The target glass is placed near the orthicon together with a very fine mesh wire (approximately 75 percent transparent) called a "Target Screen" with an adjustable potential of 0 to -2 volts de applied. The target glass is a very fine glass with very low resistance. When light strikes the photocathode, electrons are emitted, the amount of emission being directly proportional to the illumination of the photocathode. The electrons (E-) achieve an extremely high velocity as they are attracted toward the target screen. The voltage on the target glass is at the same potential as that on the photocathode.

Scanning Section. The scanning section consists of both the orthicon and electron multiplier. The electron multiplier produces an electron beam that is deaccelerated as it travels through the orthicon section. The electron beam is focused at the target by the magnetic field of the external focus coil. An alignment coil is also provided to develop a magnetic field that can be varied to adjust the scanning beam's position to correct for electron gun misalignment. Electron beam deflection to scan the entire plate is accomplished by the magnetic field of the vertical and horizontal deflection coils that are externally mounted. When the electron beam arrives at the target glass, its velocity is zero and, depending upon the potential of individual areas in the target, some of the electron beams land on the target while others stop at the glass surface and return to the electron gun. At white, the return charge potential is zero; at black, the return charge potential is

NEW

COMDEL SPEECH PROCESSOR MODEL CSP 11

A prototype of the CSP 11 has proved itself an effective communication aid on the amateur bands over several years. Its prominent feature is the instantaneous limiting action without the harmonic distortion which often makes the use of conventional speech clippers marginal, particularly with SSB transmitters. Designed for relatively insensitive high Z microphones—a gain control is provided—the unit will enhance the intelligibility of voice signals considerably under difficult conditions. "MIL" design and construction is employed throughout for high reliability and long life. Power is obtained from internal batteries (6 "D" cells—life exceeds 300 hours) or external source. Free brochure will be sent on request.

PRICE: \$111.00 POST PAID IN U.S.A. (Mass. residents add 3% tax)

COMDEL INC.-218 BAY ROAD-HAMILTON, MASS.-01982

maximum. Shades of gray are potentials between zero and maximum. These charge potentials are returned through the electron multiplier for amplification and become the video signal current.

Vidicon

The vidicon camera tube (Fig. 8) operates on the principle of photoconductivity, whereas all the other camera tubes function under the principle of photoemission. The beam hits the target with a low velocity, but not zero as in the Orthicon. Resolution is poor, and frequency response is good up to 4 MHz only. The vidicon has no shading requirement and has no burning effect. Its sensitivity is as good as the image orthicon.

The target is a thin plate, coated on the beam side by a photoconductive material. This material has a very high specific resistivity in darkness. When the beam strikes the dark portions of the target, a small charge is developed because of the high resistance. When the beam strikes the light portion of the target, the charge developed is greater because of the lower resistance of the light portions of the target. The video, a voltage function of the differences

in charge potential, is developed across the load resistor and the variations are coupled through the capacitor. With a signal current of 0.1 μ A for highlights in the scene across a 50-k Ω load resistor, the camera signal output voltage is 5 mV.

Monoscope

The monoscope (Fig. 9) is a camera tube with a fixed image and is used for camera signal test purposes. The operation of the monoscope is similar to that of the iconoscope. However, instead of the mosaic, a test pattern is printed directly on the etched plate.

. . . WB2GYS

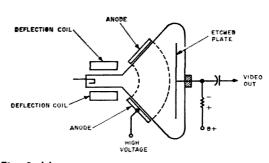

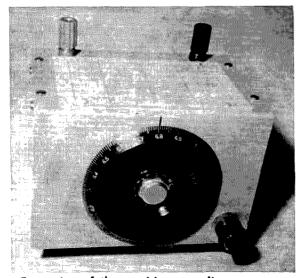

Fig. 9. Monoscope.

A Semi-Precision Capacitor

The precision variable capacitor is a very useful piece of test equipment which most hams don't have in their shacks. A capacitor of this type may be used in conjunction with signal generators and detection circuits for making many useful measurements; in fact, some measurements are very difficult, if not impossible, without a precision variable capacitor. Commercial precision capacitors are completely out of the reach of the average ham, but a neat substitute that will satisfy most amateur work may be found in the variable tuning capacitor from an old ARC-5 transmitter. These varable capacitors are extremely well made, stable, and incorporate an excellent antibacklash drive mechanism. Even at the currently high ARC-5 prices, the tuning capacitor would be difficult to duplicate.

The variable capacitors from any of the high frequency ARC-5 transmitters may be used as a semi-precision capacitor. Fortunately all of the tuning capacitors in this series of transmitters use the same range of capacitance, 34 to 154 pF. The manufacturing processes were very well controlled when these capacitors were originally made, so there is a direct correlation between capacitors from many different ARC-5 transmitters. I had an opportunity to

Front view of the precision capacitor.

check out several of these capacitors on precision laboratory equipment, and in each case the capacity at each point on the dial was within 0.5 pF of the other units; that's what I call pretty good correlation!

Most amateurs have an old ARC-5 transmitter laying around the junk box, so getting the necessary capacitor should be no problem; it doesn't make any difference what the frequency range of the transmitter is, they all have the same tuning capacitor. After you get the ARC-5, there are two ways you may proceed; you can cut down the ARC-5 chassis or you can build up a chassis similar to the one shown in the photographs. The cutup ARC-5 chassis isn't too pretty, but it's a little easier to make. The dial calibration of the completed unit won't differ between the two types of construction, so you can take your pick.

If you elect to chop down the ARC-5 chassis, remove the roller coil assembly and saw through the chassis 3% inches back from the front panel. Bend the bottom plate up at ninety degrees and trim it off so it is flush with the top deck of the chassis. Cut off the top half of the front panel just above the point where the dial index is attached. Now install two terminals; an insulated unit for the stator connection and a grounded one for the rotor. These terminals should be installed % inch in from the back edge and % inch in from each side.

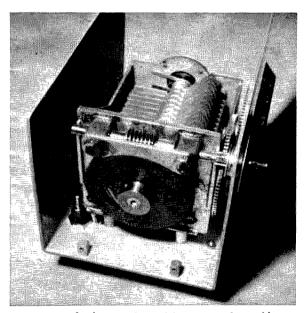

For the more complicated chassis shown in the photographs, refer to Fig 2. This chassis consists of two U-shaped channels made up from 1/16 inch aluminum sheet; one for mounting the capacitor, the other for a cover. Two pieces of hardwood clamped in a vise will help in making sharp 90° bends.

After the chassis is completed, you have to remove the tuning capacitor from the transmitter. This isn't too tough, but it takes a little perserverance and the right approach. After the bottom cover is removed, note that the tuning capacitor is connected to another variable capacitor in the rear of the unit through a flexible shaft. This shaft is pinned to the drive shaft of

the tuning capacitor. Turn the shaft so the end of the pin is facing you; then, using a small pin punch, carefully drive the pin out. if you don't have a punch small enough, an awl will do. Unscrew the large nut which holds the dial in place and carefully remove the dial. Be careful not to lose the small pin which locates the dial in the proper place. Usually this will stay imbedded in the drive collar, but sometimes it falls out. Now remove the dial lock knob. This is also pinned to a shaft and although sometimes it may be removed intact, usually it is frozen to the shaft and it's necessary to break it off with a pair of pliers. Remove the four screws which hold the capacitor to the transmitter and remove the rotor and stator connecting wires. The capacitor may now be removed from the ARC-5.

Before you discard the ARC-5 chassis, remove the large rectangular can on the rear of the chassis and note the four square studs that hold it to the main chassis. These studs will be used to hold your new chassis together. They may be removed by taking out the screws from underneath. These are the only four studs that will work; the other studs are riveted in place.

Installation of the capacitor in the new chassis should pose no problems if the holes have been drilled in the right place. Usually this is a little tricky however, since bending always seems to have a tendency to move the holes the wrong way. A little reamer will save a lot of cuss words here. Note that

Interior of the semi-precision capacitor. Note the two small square studs in the foreground which are used to hold the two U-shaped chassis together.

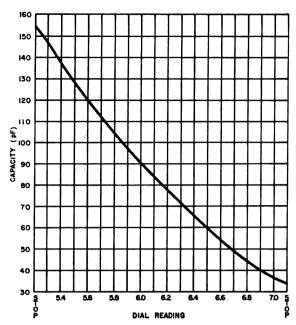

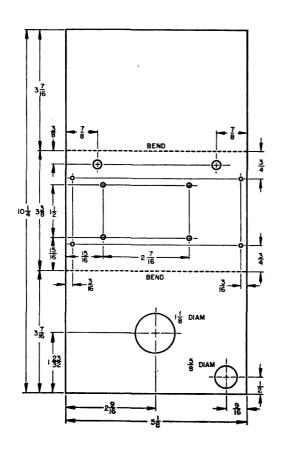

Fig. 1. Calibration curve for the semi-precision capacitor from a 5.3 to 7 MHz ARC-5 transmitter. Corresponding dial points for capacitors from 4 to 5.3 MHz and 7 to 9 MHz ARC-5 transmitters may be found in Table 1.

the chassis shown in Fig. 2 is based on the use of 1/16inch stock; the holes will end up in the wrong places if you use any other thickness. After the capacitor is in place, install a couple of insulated terminals in the holes provided, connect up the rotor and stator wires, and the semi-precision capacitor is complete. On my unit I cut out a one inch disc of aluminum and epoxied it to the knob for a skirt. It doesn't add anything functionally, but it does dress it up a bit.

Table 1. Individual calibration points for the semi-precision capacitor. This table is based on the major dial points of a tuning capacitor from a 5.3 to 7 MHz ARC-5 transmitter. Corresponding dial calibration points for 4 to 5,3 MHz and 7 to 9 MHz units are also listed.

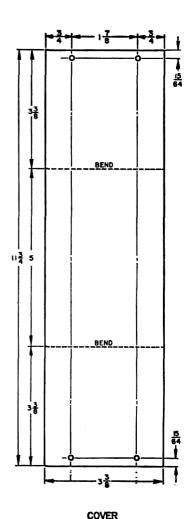

Fig. 2. Chassis for mounting the semi-precision ARC-5 capacitor. Each of these pieces is cut out from 1/16 inch aluminum and bent into a U. The dimensions will not work out properly if other than 1/16 inch material is used.

As a finishing touch you can put the calibration sheet on top of the capacitor and cover it with a sheet of thin plastic. Oh yes, four % inch rubber grommets on the bottom act as feet.

MAIN CHASSIS

If you use the calibration figures listed in the accompanying table, your semi-precision capacitor should be within about 0.5 pF any place on the dial. For more accurate calibration of course, you can borrow a lab capacitor and hand calibrate the unit exactly. When making measurements with the capacitor, the addition of six inch connecting leads will add 3 pF to the dial reading.

Now, you may ask, that I have a precision capacitor, what can I do with it? Well, there are many measurements that its use will simplify and some where its use is unique. I'll give you a few examples and let your ingenuity do the rest. The most obvious use of course is in the measurement of capacity. Connect the precision capacitor across an inductor and use a grid dipper to determine their resonant frequency. Now,

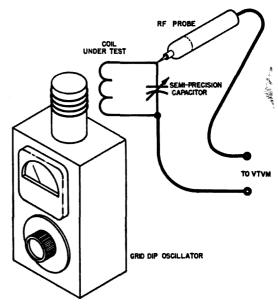

Fig. 3. Test setup for measuring the Q of a coil with the semi-precision capacitor. For highest accuracy, the VTVM should be set on its most sensitive scale and the GDO decoupled for full scale deflection.

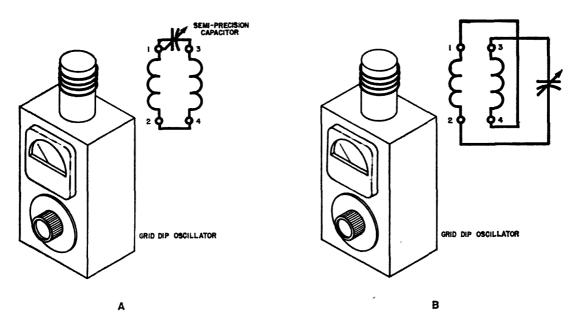

Fig. 4. Test setup for measuring the coefficient of coupling between two coils. Two measurements are required: one with the coils connected as shown in A, the other shown in B.

without disturbing the dipper, connect the unknown capacitor in parallel with the semi-precision capacitor, and tune the variable capacitor for another dip. The value of the unknown is the difference in readings on the precision unit. This method is very useful because it is very accurate, and with care quite small capacitors may be easily measured. Another method of measuring capacity is to place the precision capacitor in one leg of a bridge with the unknown in the other. A similar approach is used in many laboratory impedance bridges.

Where the precision capacitor really shines is in measurements that are difficult to make without it. The O of an inductor is one of these. In addition to the capacitor, you will need a VTVM and an rf probe plus a source of rf such as a GDO for this measurement. Connect the coil to the precision capacitor as shown in Fig. 3, set the capacitor at some convenient high value of capacitance (CR), set the VTVM on its lowest range and loosely couple the GDO to the circuit. Now tune the grid dipper for maximum deflection of the VTVM. If it pins the meter, move the GDO further away. Without disturbing the frequency of the dipper or its coupling to the coil, set the precision capacitor to a lower value than C_R so that the VTVM reads 70.7% of the voltage recorded at resonance. Record this new value of capacitance as CL and set the precision capacitor to a value greater than C_R so that the VTVM again reads 70.7% of the original reading. Record this value of capacitance as C_{II}. The Q of the coil may be calculated from the following formula:

$$Q = \frac{C_{\text{R}}}{C_{\text{H}} - C_{\text{L}}}$$

where all the capacitances are in pF.

The precision capacitor is also helpful in determining the inductance of a coil. For this measurement all you need is a grid dip oscillator. Simply connect the coil across the capacitor and adjust the capacitor for a dip on the GDO. If the dipper is set to 10 MHz, and the capacitor tuned for a dip, it simplifies the math in the following inductance formula:

$$L = \frac{25,400}{f^2C}$$

Where L = inductance in microhenries
f = frequency in MHz
C = capacity in pF

In some cases it may be desirable to measure the distributed capacitance of an inductor. This may be easily done with the precision capacitor. In cases where a small value of capacitance is used in measuring an inductor, the distributed capacitance of the coil can cause a large error in measurement. To reduce this error, measure the distributed capacitance of the coil (C_D) and add it to the test capacity (C_D in the above formula) before making the inductance calculation.

VALUABLE books from E.& E.

NEW 17TH EDITION OF THE FAMOUS

RADIO HANDBOOK

Tells how to design, build, and operate the latest types of amateur transmitters, receivers, transceivers, and amplifiers. Provides ex-

tensive, simplified theory on practically every phase of radio. Broadest coverage; all original data, up-to-date, complete. 816 pages. Order No. 167, only \$12.95

RADIOTELEPHONE LICENSE MANUAL

Helps you prepare for all commercial radio-telephone operator's license exams. Provides complete study-guide questions and answers in a single volume. Helps you understand fully every subject you need to know to obtain an opera-

tor's license. 200 pp. Order No. 030, only. \$5.75

LEADING BOOK ON TRANSISTORIZED COMMUNICATIONS EQUIPMENT

TRANSISTOR RADIO HANDBOOK, by Donald L. Stoner, W6TNS, Lester A. Earnshaw, ZL1AAX. Covers a wide range of communication uses for both amateur and commercial applications. Includes audio and speech amplifiers, VHF transmit-

speech amplifiers, VHF transmitting and receiving equipment, SSB exciters, and complete SSB transceivers. 180 pages. Order No. 044, only..................\$5.00

HOW TO CONVERT SURPLUS RADIO GEAR INTO AMATEUR AND CB EQUIPMENT

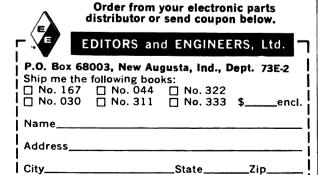

Here is a wealth of conversion data in 3 volumes; includes photos, diagrams, instructions.

Vol. 1. Covers: BC-221, BC-342, BC-312, BC-348, BC-412, BC-645, BC-946, SCR-274 (BC-453A & BC-457A series), SCR-522, TBY, PE-103A, BC-1068A/1161A, etc. Order No. 311, only.....\$3.00

Order No. 311, only.....\$3.00

Vol. 2. Covers: BC-454, AN/APS-13, BC-457, ARC-5, GO-9/TBW, BC-357, BC-946B, BC-375, LM, TA-12B, AN/ART-13, AVT-112A, AM-26/AIC, ARB, etc. Order No. 322, only.....\$3.00

Vol. 3. Covers: APN-1, APN-4, ARC-4, ARC-5, ART-13, BC-191, 312, 342, 348, 375, 442, 453, 455, 456-459, 603, 624, 696, 1066, 1253, CBY-5200, COL-43065, CRC-7, DM-34, DY-2, DY-8, FT-241A, MD-7/ARC-5, R9/APN-4, R-28/ARC-5, RM-52-53, RT-19/ARC-4, RT-159, SCR-274N, 508, 522, 528, 538, T-15 to T-23/ARC-5, URC-4, WE-701-A, etc. No. 333, only...\$3.00

To measure the distributed capacitance, set the precision capacitor to 50 pF and connect the coil across it. Couple a GDO to the circuit and tune for a dip; note the frequency and set the dipper to one half this frequency. Now restore the dip by increasing the value of the capacitance. Record this new value of capacitance (C_A) and calculate the distributed capacitance (C_D) from the following formula:

$$C_D = \frac{C_A - 200}{3}$$

Two other inductance tests where the precision capacitor is useful is in determining mutual inductance and coefficient of coupling. To measure mutual inductance, connect one of the two coupled coils to the precision capacitor and determine the resonant frequency with a grid dipper; calculate the inductance of the coil with the formula previously given. Do the same thing with the other coil. The value of mutual inductance (M) may then be found from:

$$M = \frac{L_1 - L_2}{4}$$

where L₁ is the larger of the two inductances.

To measure the coefficient of coupling between the two coils, determine the mutual inductance as shown above. Then connect the two coils to the precision capacitor as shown in Fig. 4A and calculate the total inductance using the resonant frequency method; record this value as L₁. Now connect the two coils as shown in Fig. 4B and again determine the inductance (designated L₂). The coefficient of coupling (k) may then be determined from:

$$k = \frac{M}{\sqrt{L_1 L_2}}$$

These examples show just a few of the things that the precision capacitor may be used for; most of them may be accomplished by other more exotic methods, but the use of the precision capacitor greatly simplifies things. Before I built the precision capacitor, I solved most of the problems involving inductance, mutual inductance and coefficient of coupling by the old cut and try method. The precision capacitor gives me immediate answers to these problems and saves a lot of time and frustration. In addition, it is a very versatile unit and every day I find new and unique uses for it in my shop.

... W1DTY

Down With the Rotator

Can't put up a tower? Why not use a TV telescoping mast with the rotator at the base?

Every ham can't have a tower. There are various reasons why a tower just isn't in the scheme of things. The three main reasons are—they cost too much, look too large, and take too much planning and work. For the VHF man, the solution is simple—each obstacle can be overcome.

Assume that a sixty foot crank-up tower would satisfy the requirement. The VHF beam could be at the sixty foot level, and when the tower is cranked down, it would be no higher than twenty five feet. For many of us, even twenty five feet is too high for comfortable work. Let's go one better.

What's wrong with a TV telescoping mast. Nothing at all. It will get your beam up close to sixty feet, hardly dent your pocketbook, won't look bad, and best of all, you can just about push it up and down alone. Further; when it's down, you can work on the beam at head level or at most, by resorting to a step ladder or picnic table.

The fifty foot telescoping mast can be procured at most of the radio supply stores. You can transport it home with the family car and carry it around by yourself. While the mast has washers for guying at every ten feet level, the writer has found guying at three points adequate. However, supports at four points would give greater comfort to your nervous system during storms.

It may be possible to push up the mast with a two meter beam, a six meter beam, and a CD type rotator at the top, but, when I tried it, it seemed to be too much like balancing a piece of wet spaghetti on end. As a result of a mental picture of the consequences, it was decided to put the rotator, the heaviest unit, at the base where it really belongs.

In the case of WA6SJH, it was decided to erect the mast adjacent the patio, whose roof was at the eight foot level. Accordingly, a heavy aluminum angle was formed and bolted to the patio roof siding. The horizontal face of the bracket was designed with a hole that permitted the bottom section of the mast to slide through it, but not bind.

A plumb line was then dropped through the hole center. At this spot on the ground, a four foot length of 2½ inch pipe was driven about two feet into the ground. As the pipe was driven, the top center of the pipe was periodically checked to assure its verticality. The top was then sawed off to present a smooth end. The rotator was then mounted on the pipe.

Next, by standing on the roof, the mast assembly was lowered through the hole and into the rotator and clamped. With no antennas installed, the mast was pushed up and checked for smooth rotation.

With the mast down, the guy wires were attached to the washers provided. Since only two sets of guy wires were desired, one washer was arranged to turn near the center of a section to provide better guying balance. The mast was again pushed up and the guys attached and adjusted. The guyed mast was then checked for smooth rotation. Friction from the guy rings was just right for smooth braking.

The mast was then lowered and a ten foot aluminum pipe was slid about two feet over the top of the push-up mast and bolted to prevent rotation. An eleven element two meter beam was mounted at the top and a pair of five element six meter beams below.

The assembly was then pushed up, carefully locking each section to prevent sectional slipping or rotation. One man can do the job, but two are better, since at maximum height there is push down against the guy wires and a slip at this stage would drop the top assembly ten feet.

This antenna system withstood the strong winds of the San Fernando Valley for over a year, until it was dismantled when the QTH was changed.

Rotation was always smooth and the rotator was at ground level where it could be easily serviced. . . . W3BTQ

Mobile Logs Personalized

Why not use personalized logs for your mobiling? They're simple to prepare, inexpensive and convenient.

Personalized mobile logs may at first appear to be an unnecessary luxury. However, when cost and convenience are considered, their value outweighs the slight extra initial cost involved.

Just as QSL cards may be designed especially for one person, or a stock design used at a lower cost, personal logs may be prepared in the same way. For those per-

MOBILE LOG OF WB6KFI FREQ _____ MC PWR INPUT ____ WATTS

FREQ	CALL TIME IN OUT		PWR INPUT	WA175	
CALL			LOCATION	REMARKS	

A personalized mobile log is very convenient.

sons who would like to completely design their own logs the information regarding FCC regulations and printing information will be of interest. For those who wish to follow the shortest route, the example may be used. The example may be removed from this magazine intact. Then, in place of my call, carefully transfer your call sign, in a type style and size that you prefer, from a sheet of the many dry transfer lettering sheets now available. Any art supply store and most radio parts suppliers now carry these sheets in a great variety of styles and sizes. The dry transfer process is parrecommended, although processes are available, because it is simple to use, errors can be rubbed off and started again, and yet it adheres well once applied.

Take the sample page, now complete with your call sign, to any print shop that provides offset printing service. Usually the smaller shops are better equipped and more receptive to small jobs such as this. A shop that works on QSL cards would be particularly suited for this work.

Your order to the print shop will be for: proper size offset printing, quantity as you desire, and either padded in fifties or loose, as you may wish to keep the log sheets in a loose leaf binder. If you can locate a printer who used the "Itek" process negatives the cost for production may be slightly lower than a printer who must use a film negative. The quality difference of the final printed piece is negligible between the two processes. Also, if absolute minimum cost is desired with possibly somewhat lesser quality, specify paper plates to your printer. However, keep it in mind that subsequent printings will require a

new plate, whereas a metal plate can be re-used many times.

The sample shown meets all FCC regulations for mobile operation, provided that the operator signs the log after each period of operation; or, if only one operator, he signs each page. For those wishing to design their own logs the printing cost will not change no matter how complex the design, as long as only one color is used. However, the log must show:

- 1. Date and time of each transmission. One entry for each day of operation is sufficient and can be placed across the "In-Out" column.
- Signature of each operator. This may be placed at the bottom of each sheet in the "Remarks" column together with 3, below.
- 3. Type and identity of vehicle.
- 4. Call sign of station called (whether worked or not, remember!)
- 5. Input power
- 6. Frequency band
- Type of emission. This can be placed once in Remarks column at the beginning of each sheet unless the mode changes before the sheet is completed.
- 8. Approximate geographical location of the mobile station. Normally one entry for each station worked is sufficient to comply with regulations as "US 80, ten miles W. Reno." This is the type of location identity that is legally required, rather than what is frequently heard such as "W6 . . . mobile W7." However, if you are covering a great deal of distance fast you are wiser to enter something like "US 80 between Reno and Fernley" for instance. The regulations say "approximate" and Webster says that is "nearly correct or exact", so there is some leeway allowed.

9. Messages handled. If traffic is handled, the information regarding their numbers may be placed in "Remarks".

The foregoing outlines what you must enter in the log to abide by the regulations. A review of Sections 12.136 and 12.137 should be made if you are in doubt about any portion of them.

A typical cost for printing 100 sheets is about \$3.00. Subsequent printings by the same printer will be less. Be sure you request return of the negative and plate he will produce. The plate is all that is necessary when requesting subsequent printings.

This log is very convenient to use on the car seat right beside you (provided you are not a southpawl). No rulings across the page are provided because it is too difficult to follow a straight line in the log at the same time as you follow one on the road. In fact, if necessary, it is quite easy to keep a respectable-looking log with barely a glance. For safety reasons, obviously, the best policy is to have the second operator keep the log.

By following the procedures given, you may also prepare your own personalized fixed station logs. In this case, rulings and additional information may be added to any extent you desire. Just remember to provide all information that the regulations require. As in the case of the mobile log, no matter how many items are added, your printing costs will remain the same for the same size sheet.

For those who would just like to purchase the log sheets without any of the preparation described, the author has arranged to have these made available, with your call imprinted, from WA6GMD at \$3.00 per hundred, including postage. Send requests to WB6KFI at address shown at beginning of article.

Attaching Shafts to ARC-5 Tuning Capacitors

The variable capacitors from ARC-5 receivers are very popular in amateur construction because they are well built and relatively inexpensive. There is one inherent problem though: how do you connect a conventional ¼ inch shaft to the splined shaft? The best method I have found uses a short piece of masking tape, some epoxy cement and a standard ¼ to ¼ inch shaft coupler. First of all, take a strip of masking tape

about ¼ inch wide and wrap it around the splined shaft to build it up to ¼ inch diameter. Put a little extra on and take it off turn by turn until it fits snugly into the shaft coupler. Now coat the tape and one end of the coupler with epoxy cement and put them together. In 24 hours you will have a firm coupling that may be attached to a standard quarter inch shaft.

Add a Crystal Filter to Your Receiver for less than \$10

Crystal filters are a luxury found only in the more expensive receivers. For some unknown reason, most literature available to the ham and the tinkerer sheds little light on how to make them. The advantage of having a crystal filter is unquestionable, especially with the crowded conditions of today's ham bands. The filter shown in this article is intended mainly for the CW man although it will be of some use in SSB. It has a continuously variable bandwidth from about 200 hertz each side of center, (or less) to somewhere around 3 kHz. A phasing control moves a sharp rejection notch through the passband virtually eliminating interferance almost on top of the signal you want.

Fig. 1 shows the passband of the filter. The steepness of the sides really depends on how carefully you build it. But even a poor job of construction can be a tremendous improvement over a low priced receiver with no filter.

Its operation is really quite simple to understand. Remember that a crystal looks, electrically, like a series tuned circuit with a very high Q. Also, the Q of the whole thing depends on how you load it. Finally, the Q determins the bandwidth, $(Q = {}^{t}/{}_{bw})$. Fig. 2 is a schematic of the filter. Part values will be given shortly. The crystal is ground to the *if* frequency. The *if* can feeding the filter has a heavy load resistor on

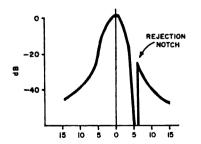

Fig. 1. Typical crystal filter curve at 3 kHz pass band.

it. (R1) This makes its passband very broad so the filter is the main controlling factor for that stage. When you don't want the sharp bandwidth the switch (S1) shorts out the crystal. A parallel tuned circuit (L1-C1) loads the crystal. The potentiometer (R2) varies the Q of the tuned circuit, thereby controlling the bandwidth. The variable capacitor (C2) balances out the capacitance of the crystal. The position of the notch is influenced by this control.

All parts for the filter should be positioned to keep lead length at a minimum. Otherwise you will have problems. (i.e. it will oscillate like a bird!) You would be wise to build the filter in a 2 x 2 x 3 Minibox and run shielded leads to the tie points. Controls can be brought out to the front panel by shaft extensions. Ground all your shields only at the filter end and then run a separate ground wire to the common point in the *if* section. If the receiver has two or more *if* stages, insert the filter at the input of the last stage. If the receiver has only one *if* stage, use a larger Minibox and build another.

You will have to doctor one of the cans so it can feed the filter. My suggestion is that you remove the can from the receiver and mount it on the filter box. This will also leave a convenient hole to bring leads in. Now, most if cans have their tuning capacitor built into the base. This has to go. If you break off the lug which connects to the internal capacitor. Then you can build up the base again with epoxy resin. If the can is tuned with a mica capacitor mounted where you can reach it simply cut it out and you're in business.

The two series capacitors, Cc replaces the tuning capacitor of the can. Unfortunately most manufacturers don't tell you what this capacitance is, so you're going to have to have to diddle. Trial and error is the best method. Connect the can back into the receiver with the capacitor removed, tune in

a strong station such as a local broadcast station, and try different values of fixed mica capacitors. The value which gives the strongest signal is your resonating capacity. If you have a National receiver with a 230 kHz *if* you will find 180 pF to be close enough. When you find this value, make each Cc twice that amount. (In the above instance, two 360 pF capacitors were used.)

O.K., so you build the thing and install it. Now you have to align it. If you have a signal generator you're lucky, but suppose you don't? Don't throw in the towel yet. A true ham knows how to make do. You need a steady CW signal (No modulation). You can use a VFO if you have one. However, if you're a poor man like me, use a cheap AM radio! Set the radio within handy reach and tune it to the top of the broadcast band. Take a single wire from the antenna lead of the receiver and let it dangle inside the case of the AM radio. You will find a nice strong CW signal somewhere around 2.055 MHz.

Peak up the can with the crystal shorted out. Then tune C1 for maximum output. Now set R2 for minimum resistance (widest bandwidth), unshort the crystal and peak up the whole thing all over again. I will warn you at this point that the tuning is awful sharp. When you throw in the crystal re-tune your signal source, or the receiver front end. Do it very carefully. With R2 at maximum, the signal will almost seem to ring. (I assume you are using the CW oscillator.) It will be very critical to tune and will sound very peculiar to one who is not used to crystal filters.

The filter has the narrowest passband when the load is heaviest. Just the opposite to what you might expect. The following

table gives parts values for 240 kHz and 455 kHz. The calculation of these values involves a lot of hairy math. If you are a whiz at math, or have had a couple of years of college, you will find the whole design process in the Radiotron Designer's Handbook. Otherwise forget about computing it yourself.

The filter is not too difficult to install. The input can of the filter is connected to the output of the preceding *if* stage. The filter is then capacitive coupled to the following stage. Notice that the bypass which was at the low end of the can before installing the filter is removed altogether. The resistor to the AGC line now goes directly to the grid, thus providing a dc return path. Bring a ground lead from the filter to a ground point in the *if* strip. Shield all leads connecting the filter into the circuit. Ground the shields only at the filter end. Mount the filter in such a position as to insure shortest leads.

The crystal is of the same type used for frequency control. When you order it, specify a series resonance at the *if* frequency. You can get one quite reasonably from Abbott Electronics, 85 Elm St., No. Woburn, Mass., if your local supplier can't get it.

If you buy a new if can, the supplier may be able to find out the value of the internal capacitor. This will save you some work, since Cc must be twice this value. Meissner makes a pretty good can as do quite a few others. The switch should be a SPST rotary type. You can get that in the five and ten. As for shafts and couplers, most suppliers have an ample stock to fit most needs. National has a wide variety of these.

.. WIUSM

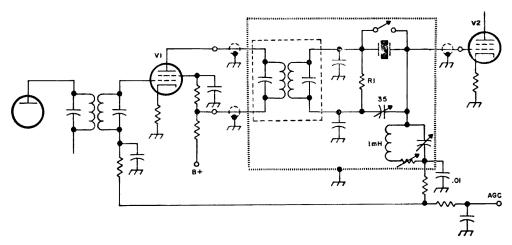

Fig. 2. If strip modified to include a crystal filter. R1 should be 3 k Ω for 240 kHz or 2.7 k Ω for 455 kHz. R2, 50Ω at 240 or 750Ω at 455.

A Reactivator for the Semiconductor Activator

A simple charger for automobile storage batteries.

Semiconductor circuits in general require a stable low-impedance source of power. While well-regulated low-impedance supplies can be built, and usually are included as an integral feature of the equipment, a separate power source is quite attractive for numerous reasons. Perhaps the most important is the feeling of confidence that if trouble develops, and it usually does, the trouble is confined to the circuit and not in the source of power.

Dry cells and the like are out as primary sources of power. They have fairly high impedance, intermittent connections if a pressure plate is used as with numerous flashlight cells, and can be quite noisy. The lead-acid storage battery is preferable in many respects. It can withstand heavy loads without budging due to its low internal resistance. It also has a very low ac impedance which is very suitable for powering amplifiers which may have regenerative (or degenerative) effects when used with less efficient power sources. But, the lead-acid battery does have a few disadvantages. It requires charging, is messy, and is rather expensive. Read on.

The first problem is getting the battery. Most gas stations have a few old trade-ins lying around. Casually pick out one that appears to be in fair condition and ask them to give it a short quick-charge to see

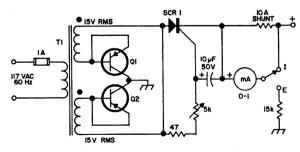

Fig. 1. Simple battery charger. Most of the components are not critical. They're discussed in the text. The dots by the transformer windings indicate the polarity of the rewound secondaries.

if will absorb the soup. On the way to the charger it wouldn't hurt to accidently drop the battery in a carefully planned trajectory on its bottom edge. This will serve to break loose the chemical build-up which frequently tends to short out cells. An old style battery with the lead straps exposed on the top is much better for obtaining tapped voltages. The second problem, the messy deal, is simple to overcome. Build a box out of old scrap lumber and hide the thing. Be sure the bottom is nailed inside the sides, rather than under them, so it won't fall out. Add a couple of pieces of wood for hand-holds. A top cover will help to keep the dust and dirt out, but be sure to leave ventillation holes for the gas to escape. We still have the third problem to overcome, so let's charge on.

The complete circuit is shown in Fig. 1. It uses a pair of obsolete germanium transistors as rectifiers, and an inexpensive SCR as a current regulator. Manual control with a potentiometer is provided for current conditioning. Metering to check the charging rate and the battery voltage is accomplished with the standard 1 mA indicator.

The transformer selected was originally rated at slightly over 60 watts. So—to avoid complications—a one ampere 3AG fuse was selected. There is some surge on turn-on, but the Slo-Blo fuses always seem to take out the transformer too, so a regular quick blow fuse was used. After you build a transformer personally you appreciate the need for protecting it properly.

The transformer used is not listed by name or number, although it was a very popular brand. The essential characteristics are a good power rating and ease of disassembly. This one had windings of 5 V at 2 A, 6.3 V at 3 A, and 350–0–350 V at 90 mA. It adds up to around 62 watts or so. It also adds up to a future life as a paper weight in this day and age. So, off with the secondarys. Cut off the high voltage one. When unwinding the 6.3 V and 5 V

sections count the number of turns. This is helpful in determining how many turns to put back on. Most standard transformers have the primary as the bottom or inner winding. Some special ones have the primary as the outer winding and should be avoided like work.

For up to ten or fifteen amperes, #18 wire is perfectly suitable. It only carries the current half the time, since a full wave rectifier is used. Use some fairly rugged paper for insulation between the layers. This helps to keep the winding smooth. On reassembly, it may be found that a few of the iron laminations won't fit in. Don't worry about it. If you used ordinary care in winding, stretched the wire to straighten it, etc., you now have a good quality suitable transformer. So put a load on it and connect it to the power line. It buzzes? Coat the laminations with lots of shellac.

Rectifier voltage drop is an important consideration at these potentials. If silicon rectifiers are used instead of the inexpensive germanium transistors, a few more turns must be added to the secondary windings. PNP germanium transistors are about the cheapest type low voltage rectifiers available today. They are mounted directly on the bare metal of the case, without mica washers or the like, to provide low thermal resistance. Delco 119-0016 were used but any suitable 10 or 15 amp types are ok. The SCR is also an oddball. Its ratings are required to be only 30 volts or thereabouts

breakdown and 10 to 15 amps conduction. It is most easily mounted directly to a flat piece of aluminum as a heat sink, and the heat sink then insulated from the enclosure. The power supplied to the SCR regulator is not actually dc, but rather a full-wave rectified ac. The simple resistor-capacitor network allows setting the gate turn on point as desired for the required current output.

Metering is done by an ordinary inexpensive 1 mA meter. A 10 amp (or 15 amp) shunt is easily constructed by making an air wound coil of #18 or #16 gauge wire. Measure it carefully, after consulting a wire table to find the resistance per unit length. For instance, with a 1 mA meter of 100 mV sensitivity, 9,999 mA must go through the shunt with the same voltage drop. It works out to about a dozen turns of #18, an inch diameter. Don't try to switch the current. This will create troubles. Switching the meter also allows checking the battery voltage. This information, while of doubtful value, does prevent errors such as reversed connections.

It will be found that the charging current is initially quite high, then tapers off to a steady value. No provision is made for an automatic cut-off so it is necessary to do that by hand. Unplug it. It should be unplugged anyway when using the battery for testing out circuits. Avoid AC ground loops.

Antipodal Bearings

Several months ago, in reply to a comment about a QSO being long-path, VQ9TC remarked, "There are two long paths!" It may be a long way from W6 to VQ9, but it is a problem to determine where those paths are. An inspection of a great-circle chart will disclose that one longitude and one latitude occupy the entire border of the chart. This makes it clear why a station at your antipode may be heard from any direction that provides a good signal path, even though this path is neither "short" nor "long". When the antipode of a desired point falls close to your location, a small difference in the place on which the chart is centered, will make a very large change in the indicated bearing.

Even though you do not have a world

globe at hand, there is a quick way to determine the bearing of a place close to your antipode. First, pick off the latitude and the longitude of the distant place. Consider the South latitude as North latitude. Subtract the longitude from 180 degrees. distant point.

Let us take an example. The Callbook's World Atlas shows Kerguelen Island, FB8XX, at about 47S and 69E. Subtracting 69 from 180, we determine the antipode of Kerguelen to be about 47N and 121W. This falls approximately on Seattle, Washington. It is easy to appreciate, therefore, that the bearings from various points in the U.S.A. to Seattle differ drastically. A small change in the location of the distant point (such as by using Heard island instead of Kerguelen) also can make a surprising change in the bearings from your location.

The Ancient Marriner

An antenna tuner for co-ax-fed Tri-Band Beams

If you have tried all of the other tuners for matching your transmitter to a 52-ohm coax-fed beam with no results, try this one. Beam antennas generally are not very broad band. They resonate at one particular frequency and at that point the SWR might be 1:1. As tuning departs from that resonant point the SWR increases. There may also be other causes for high SWR, the amateur may have taped his coax to the leg of the metal tower and un-balanced the line. This article is not written to discuss means of getting rid of SWR but how to live with it. It is doubtful the efficiency across any amateur band will fall off to where it makes very much difference in signal strength. This article is concerned with, however, how to make sure the transmitter is looking into 50 ohms at all times. This will assure the antenna load will absorb the power out of the tubes so that they will not have to be replaced after you hold the key down.

Several years ago no one would give much thought to SWR on the feed line because the higher plate dissipation tubes were used in the output of the transceivers. As manufacturers started to use small TV sweep type tubes in the final, the operator had to be careful that he did not burn up the tubes.

Check your rig. Turn out the shack lights, load the rig up and press the key with

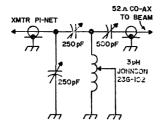

Fig. 1. A tuner for coaxial-fed antennas can help your transmitter see a 50-ohm load even though it has no effect on the SWR of the line running from the tuner to the beam.

the frequency tuned off from the resonant frequency of the beam. Observe a thin red line on the plate of the tube. Now connect a 50-ohm dummy load in place of the antenna, load up the rig and press the key. It is likely that the tubes will stay cool. This should prove to the operator that steps should be taken to do something about his antenna set-up before he has to replace the final tubes.

One solution to the problem would be to use some kind of a beam that could be tuned to the operating frequency. Generally this is not possible and the amateur is stuck with his coax fed beam. The solution now is to use a tuner so that the transmitter looks into 50 ohms regardless of the SWR on the antenna feed line.

The design of this tuner was just stumbled on by accident while fussing around with the 50-ohm Trans-Match described in the ARRL handbook. The split-stator capacitor was replaced with separate capacitors, and it was found that the SWR could be tuned down to zero. The values of the variable condensers should be at least 6250 pF for the 20-15-10 meter bands. It was also found that using a roller coil a better adjustment could be made for the null position. Once the minimum spot is found for one frequency in the band, only a slight adjustment is necessary with the roller coil to bring the SWR down at the new frequency.

Tuning proceedure

First tune the transceiver by using a 50-ohm dummy load. Next switch from the load to the beam antenna and use only a minimum of output, or just enough to see the SWR indicating. Adjust all of the variable condensers to a minimum of SWR, and also adjust the roller coil, which takes about three turns on ten meters and four turns on fifteen meters. The coil is one inch in diameter and uses #12 wire.

NEW CW MONITOR & CODE PRACTICE OSCILLATOR

Improve your CW sending

- MONITORS TRANSMITTER'S RF OUTPUT WITHOUT ANY CONNECTING WIRES
- TRANSISTORIZED
- KIT OR WIRED
- BUILT-IN SPEAKER
- LOW COST

Model OM is a combination code practice oscillator and C.W. monitor. It monitors the transmitter's RF output WITHOUT any connection to the transmitter. It may be used with any ham transmitter or transceiver. There is a tone control and headphone jack on the front panel. Model OM contains 2 transistors and 4 diodes. Size 6" x 3" x 2".

Model OM

AMECO EQUIPMENT CORP.

Div. of Aerotron, Inc. 178 HERRICKS RD., MINEOLA, L. I., N. Y. 11501

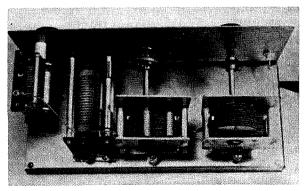

No tuner is used on 40 meters because the dipole cut to mid-band seems to do the job. The eighty meter band is 500 kHz broad and a dipole does not work across the whole band. Here it is better to use a center fed zepp and a match box tuner, unless the operator is only interested in the phone portion of the band.

Conclusion

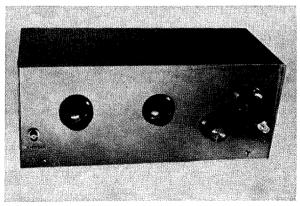

If you own a transceiver with small sweep tubes, and operate CW with a long duty cycle, just make sure the tubes are not getting hot from too high an SWR on the line. On the air fellows will tell you the pi-network will match the antenna, or they have never had any trouble. The pi-network, however, can't make a non-resonant antenna take out the power, and it will be dissipated in those cherry red plates. To save your tubes a coax tuner should be used.

Maybe someday in the future, beam construction will incorporate a way of resonating the driven element to the operating frequency. Let's hope so, then there will be no need to keep worrying.

W6BLZ

Inside of the coax antenna tuner built by W6BLZ.

W6BLZ's coax antenna tuner.

Climbing the Novice Ladder

Part III: Judy and Joe are really pitching!

After completing their code practice oscillator in FN's shop a few weeks back, Joe had stopped at Judy's place before going home. Her mother greeted him cordially and called Dad in from his cabinet shop on the rear of the lot; Judy's father was well known in the neighborhood as a master eraftsman in wood. Joe immediately felt at ease with this middle-aged couple; it was obviously a happy family which also included Judy's brother now away at school.

It being lunch time, Mrs. Mansfield insisted that Joe remain and share it with them; they could discuss their code practice arrangements during the meal. When Judy explained that she and Joe would like a quiet corner table somewhere that they could use several times a week for awhile, her Dad immediately offered a corner in his plywood storage shed which already had a long built-in, shelf-like table.

"Swell," Judy exclaimed, "it's still summer so we won't need any heat and there's a big window right over the table so we'll have plenty of light; I'll show it to you Ioe right after lunch".

Inspection of the code practice 'shack' confirmed Judy's opinion and as they had already arranged to get together every other afternoon until school started, Joe mounted his Honda and headed for home. The arrangement proved ideal. When Joe appeared in the early afternoons, not forgetting to pick up a few bottles of Coke, both youngsters industriously applied themselves to mastery of the code with occasional conversational rest periods and the always welcome 'snack'. It was not too many days before their efforts bore fruit; neither was giving more than an occasional glance at the printed code chart in the little book which FN had loaned to Joe. Their young minds quickly absorbed the dot and dash combinations which made up the various letter characters . . . figures and punctuation came a little harder. Diligent applica-

tion with the emphasis on these soon eliminated that stumbling block and it wasn't long before they were not only identifying the individual letters as sent by their partner, but short simple words as well. Toward the end of the second week Joe said, "Say, Judy", it's about time we went back to see FN and let him check our progress; he asked us to, you know. What say we peddle out there Saturday morning?"

"Fine with me Joe," Judy returned, "I'll meet you out there about 9 o'clock . . . OK?"

"Suits me," Joe replied, "see you then . . . s'long and . . . 73"!

"73 yourself OB and CUL" was Judy's very much ham-flavored reply. They had found these ham abbreviations in FN's little book and had memorized a few of them; 'OB' for Old Boy, 'YL' for young lady, 73 for best regards and 'CUL' meaning see you later . . . quite a string yet to go but they were picking them up as they went along.

Shortly after nine Saturday morning Joe had arrived at FN's shack and Judy was not far behind. They were welcomed with. "Well; you kids haven't been out for a couple of weeks now . . . how're you getting along with the code?"

"Well Gramps," replied Judy, "we think we're doing pretty good; Joe and I can talk to each other a little bit now with the key".

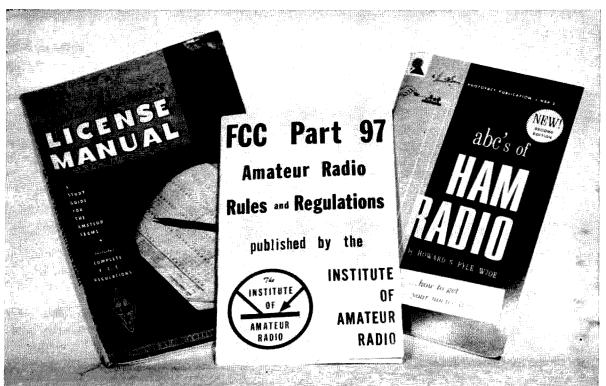

'Sounds good to me," said FN, "let's set up a practice set here on my bench and see just how good". So saying, he lifted his CPO from a shelf and plugged in the headphones from his shack. "You bring another pair of phones?" he questioned.

"Oh yeah", Joe replied, "they're in the carrier on my Honda . . . I'll get 'em". He returned in a few moments and plugged them into the dual clips on the CPO.

"First," said FN, "let's see what your sending sounds like; here Judy, send me the first line on this card", handing her an advertising circular. Slowly and carefully, Judy made it without error. "Now Joe, you send the same line" which Joe did but spoiled a letter 'S' by inadvertently adding a dot, making an 'H' of it. "All right," said FN after pointing this out, "let's sit down now and talk about sending before I see how well you can copy which is what we call it when we are receiving from the other guy". Joe pulled out FN's thinking couch and he and Judy settled themselves while FN wheeled his office chair from the shack and joined them.

"Judy, you've got the makings of a good 'fist' . . . that's how we refer to a fellow's sending style. Right now you're a wee bit hesitant . . . not quite sure of yourself. That's evident from your dots which are a bit too light. Make 'em more firm . . . like this" and FN reached over to the bench. handed them their headphones and made a string of dots on the key. "See what I mean? Don't forget though that the dot is just one third the length of a dash . . . not necessarily by 'micrometer' measurement but so that it will sound that way to a listener; try it now". Judy reached across Joe to the bench but FN stopped her with, "Uh uh . . . you can't send good with your arm in thin air Judy; get up and rest the big muscle of your forearm on the bench . . . push your key back about 18" from the edge. That's better, try it now . .. make a string of dots . . . no, no . . . don't quiver them out fast like that . . . take it slow but firm

... there, now you've got it. Now make several dot letters, 'I', 'H', 'S', and the figure '5'. That's much better now; keep it in mind. Aside from that you are doing all right although you both are a bit tense in your grip on the key; I'll give you a tip on that in a minute. Now Joe, you go ahead and send the same line on the card". Profiting by FN's advice to Judy, Joe through with better dot formation but showed a tendency to drag his dashes a bit now and then making them closer to four dots in length rather than three. Pointing this out to him FN said, "Uniform Joe . . . uniform . . . make all of your dashes the same length. Go ahead now and send me the letters 'O', 'M' and a few zeros several times" which Joe proceeded to do. "That's better, Joe, but practice it . . . your dashes still vary a bit . . . watch it and have Judy check you on it from time to time and you check her for light dots too. Now let me give you that little tip to break finger tension in holding the key. In the first place, don't grab it like it was going to run away from you nor simply tap it with one finger; just a firm, light grip does it. I'm not going to try to tell you how to hold the knob . . . just grip it in the way that's most comfortable for you. A lot of manuals will detail just what fingers to place where . . . skip it for now. As you

FN recommended that Judy and Joe get these three inexpensive booklets to help them learn the things they'd need to pass the novice exam.

progress there's a 99% chance that you'll slip into the "thumb, forefinger and middle finger" grip that is used by practically all experienced operators both amateur and professional. Don't try to rush it though . . . let it develop naturally. Every fist has a distinctive style of its own; most experienced operators can immediately identify what operator is holding the key even before he signs his call letters, just by his style of character formation, if he has heard or worked him a few times previously. It's a good deal like writer's style in that respect; they follow much the same pattern. I'm drifting away from the point though; holding your fingers stiffly straightened out will soon tire your sending hand and you'll eventually develop what we call glass arm, a form of telegrapher's paralysis which will make sending extremely difficult and your character formation very hard to read. Before you do any sending again, hold a little rubber ball, a plum, small orange or even a wad of paper . . . something about the size of a golf ball . . . in the palm of your hand and keep it there while sending. It will help keep your fingers rounded and prevent tension from developing . . . this way, see?", and taking a scrap of old newspaper from under the bench he crumpled it into a ball, cupped it in his palm and sent them a few characters on the key, then had each of them try it.

"Gee, F. N., it really helps, doesn't it Judy?" said Joe.

"Oh yes . . . it seems much more natural and it's easier to send" and she rattled off a few characters to prove it!

"OK then," said FN, "so much for sending; now let's see how well you copy. You put the headphones on . . . I won't need any while sending. Here's a scratch pad and pencil for each of you. I'll send you just straight English from this page in my book; see what you can do with it". FN sent for perhaps two minutes at a rate of about 5 words a minute. Long practice enabled him to judge speed pretty accurately. He stopped sending and they passed him their copy. After a few minutes thoughtful study, FN announced, "Well, that was pretty close to five words a minute which will be what you'll get in your examination. Neither of you copied it solid which is a term we use to mean every letter; you both made a few misses here and there particularly in the few figures and common punctuation I sent you. How come you missed all three periods Judy? Think a minute and you'll recognize the characters for a period as being simply three letter A's run together to make one character. Joe got all the periods but his weak letters seem to be 'Y, 'F' and 'L'; you didn't do so well on the 'L' either Judy; both of you seem to get 'F' and 'L' confused. When I sent you 'L' you both wrote 'F' every time! True, they are opposites in that 'F' is 'dit-dit-dah-dit' and 'L' is 'dit-dah-dit-dit' . . . 'F' turned around. Your job will be to untangle 'em . . . choose words with lots of these two letters when you practice. Also, try the simple words you learned when you were babies; dad, sis, mommy, baby, boy, girl, dog, cat, etc . . . that kind of stuff; lots of good practice material there.

"Well, you've shown me that you aren't quite equal to five words a minute yet which was hardly to be expected in this short time but your progress is excellent. Suppose we see now at just what speed you can make solid copy. I'll send for exactly two minutes by my stop watch and at a little slower speed using different words. Ready? go! Two minutes of silence except for the faint click of the key. Both kids turned in their papers and FN found one error on Joe's . . . the 'Y' again; he had written 'X'; Judy showed two errors but she got both periods correct this time. Her slips were between 'U' and 'V', only one dot different. FN then counted characters and said, "I was sending just a mite over 3½ words a minute . . . not quite 4. Judging from that I'm going to credit you both with solid copy at 3 words per minute; not a bad showing in two weeks. We'll drop the code angle now and discuss some of the other requirements for your license exam.

"First off, let me tell you a bit about the 'formalities'. You may think as a lot of budding hams seem to, that you will have to appear among a group of strange applicants and be examined by a Federal officer in totally unfamiliar surroundings. Any group examination as you know from your school tests, creates a mild form of nervous tension which has a tendecy to interfere with your thought track to some extent. In a radio code examination particularly, this is often responsible for failure to pass the first time and sometimes even the second even though the applicant has appeared qualified after having been checked by a friendly ham. The novice class however, gets a real break; they can be examined right in their own home or at any other place which both their examiner and theirself mutually agree upon. And, the examiner is not a Federal officer nor anyone else special; he (or she) can be anyone 21 years old or more who holds a valid amateur General class license or higher . . . even a member of your own family if he meets these requirements! I can act as your examiner, so can Larry . . . any ham with a General class ticket or better . . . you can choose your own examiner. You'll find all of the information in this little pamphlet and you can get a copy free by simply sending a postcard to 73 Magazine, Peterborough, N. H. 03458 and asking for "FCC Part 97, Amateur Radio Rules and Regulations". I suggest that you both do this; I'll loan you this copy until yours comes".

"What I'd like to do is this;" FN continued. "I would prefer that Larry, if he is willing, or one of the other qualified club members conduct the examination for Judy and I'll examine you Joe; that way neither of you will have a family examiner which will help condition you for your General exam which must be taken before a total stranger . . . the FCC engineer who will then examine you. If that's OK with you kids, suppose you ask Larry, Joe, if he will take Judy on when she is ready; I'm sure he will . . . you know him don't you Judy?"

"Oh yes, Gramps, he was a senior when I entered high school and I knew him slightly then and I've talked with him a couple of times since at the ham club . . . he's fine with me for an examiner".

"Good" FN replied, "you see what Larry thinks then, eh, Joe?"

"Oh sure . . . he'll do it though I know" said Joe.

"All right then, so much for the examination; it will be a few more weeks before either of you will be ready but we might as well start laying the cards. Now let's talk about another phase; what many hams refer to as the technical part of the examination. It really isn't technical in the true sense of the word . . . you Joe, with a couple of years of high school physics behind you and your own electrical experiments at home, won't have a bit of trouble there I'm sure. Judy may be a bit puzzled when a few terms such as watts input, final amplifier and such come her way . . . you can coach her here, Joe, as you run across unfamiliar terms in your study. For study material I'm going to suggest that one of you pick up the little book, Radio Amateurs License Manual, put out by the ARRL . . . that's the American Radio Relay League, a club to which about a third of the American hams belong. You'd better get that one, Joe, and Judy, you get a copy of the ABC's of Ham Radio published by the Howard W. Sams Co. With these two books which you can exchange between you, you'll find much more than you'll need to know for the exam and the little pamphlet on regulations you are sending for will take you over that hump. Your exams will be of the multiple answer type where you just make a mark opposite to what you think to be the correct answer among a number which you'll be given with each question. You won't have to draw a single schematic or wiring diagram; just check off your answers.

"Pay particular attention to the laws and regulations applying to radio amateurs; all three publications will give you these. You see, the FCC must be assured by your knowledge of these that you will be capable of legally operating an amateur radio station if a license is granted you. Knowing the rules is largely a matter of memorizing but you're going to have to read them a number of times so that you can intelligently answer questions on them. You don't necessarily have to memorize them word for word but get the meaning of each clear in your mind so that when you get a question reading like this; 'What is the penalty for transmitting a false distress signal? you will immediately know which of the several possible answers given you on the sheet you should check as the correct one. You'll find plenty of sample questions and answers in both the License Manual and the ABC's book as well as a wealth of additional material which will clear up many points of ham operation for you . . . pick up these books as soon as you can . . Jim Turner's Electronics Supply Co., here in town, has them both.

"Now you kids run along, pick up your books and keep on with your code practice. I'd like to see you back here in a couple of weeks and if you apply yourselves well you should both be doing your five word a minute or better in that time. Next time, after checking you out on code, we'll talk a bit about the equipment you're going to need to put a station on the air when you get your licenses. For now then, CUL and 73".

Off they went, tossing back like real dyed-in-the-wool hams, "73" to you too ol' timer ... BCNU!"

. . . W7OE

Terry Banks K3LNZ 426 Orange St., SE Washington, D.C.

Portable Operation Without Tears

The author was bitten by the Portable Operation Bug early in his ham careerin fact a mere six weeks after first being licensed. The first mild infection was contracted from a publication called "QST", which urged us all to take to the hills during an event called Field Day. The disease has now reached it's most virulent form, and friend K4LHB has been infected as well. This results in such things as operating the Ianuary VHF Sweepstakes from mountain-tops, impromptu trips to investigate various high places, and even the expenditure of hard cash for various items which by no stretch of the imagination would be handy around the home station. A great many lessons have been learned (most the hard way) which are presented here for when the bug bites you.

The location: For Field Day, a "DXpedition" to a rare county (that's right, no "r", just "county") or just the urge to get away for a day or a weekend, the main considerations are (1) a quiet location, with a minimum of man-made noise such as ignition, TV oscillator radiation, fluorescent lights, neon signs, etc., (2) a source of power (which may conflict to some extent with the requirement for no noise) and (3) availability for hamming purposes -both accessability and permission to use the location. For VHF operation, add altitude-the more the better. It is best to scout several prospective locations in advance, preferably with mobile gear in operation. Excellent maps are available from the government (Note 1) to aid in determining height and locating access roads. Permission is best obtained by stressing that the use of the location will be in practice for operation on an emergency basis should a disaster strike the area. U.S. and State parks can usually be used, but permission will usually require a prelimi-

nary inquiry followed by a formal letter to the main office, so start early.

What equipment? Portability sounds like the first thing to consider, but experience puts it well down the line, to be considered only in relation to what is available for transportation and operating space. Reliability comes ahead of everything else, and anything that isn't 101% dependable at home should not be taken out where erratic voltage, temperature variations and possible high humidity (not to mention being bumped around a bit) may be encountered. Compatability must also be considered when using gear from several different sources, as frequently happens. Get the interconnections made and checked out in advance.

Power: For any serious operating, 110 volt AC power is still almost a must. If a power line is available, it may well have generally low voltage and poor regulation, so a husky Variac might be necessary. If a "putt-putt" is used, it shoud be checked for correct speed by running an hour or so under full load with an electric clock connected. Compare this clock against WWV or another clock connected to the local power line. The generator should be adjusted so that the clock connected to it does not lose any time, which then assures that the minimum speed (full load) will produce 60-hertz current. Lower frequencies will cause heating of transformers and poor filtering of dc voltages, whereas any higher frequency will have a negligible effect on the equipment. This is also a good time to check for noise from ignition and arcing at the commutator, especially if a borrowed or rented generator is to be used. Plan on a minimum of 100 feet beetween generator and gear, with a hill or other obstruction in between to keep down both electrical and exhaust noise. A voltmeter to watch for extremes of voltage should be in use at all times, plus some means of disconnecting all the gear at once should the generator overspeed or bog down. For this purpose, any old meter with a rectifier diode and enough resistance in series to bring normal voltage to a logical spot (usually center) on the meter scale will serve. Storage battery power is more practical now than it was a few years ago. what with 12 volt systems, alternators, and transistorized de to de supplies, but there are still disadvantages such as forgetting to start the car before the battery runs down too far. Dry cell power is obviously impractical unless the only means of access is on foot, which makes this type of operation not worth the trouble unless you can find a very rare location and/or a goshawful high hill.

Antennas: The usual things apply here, but everything is temporary, so lots of rope can be used to put things up and hold them there. On a hilltop, there is rarely any benefit to be gained by going any higher than is necessary to get the antenna away from ground effects. For some locations, it is practical to set up the antennas a day or more in advance, since this usually amounts to almost 50% of the work of setting up. For large operations, it is best to select the best qualified "antenna engineer" to oversee the whole operation, including checking that feedlines and rotor control cables are connected before giving permission to "hoist away". My previous article on antenna raising in 73 for November 1964 gives many ideas that will help get the antennas up in the air with the least colorful language and damage.

Spare gear and parts: Anything available can be taken along to keep the station on the air if the main gear fails, but this can be carried to extremes. For example, a Gonset Communicator makes a real nifty spare for 6 or 2 meters, whereas another transmitter, receiver, modulator, and power supplies for all would be practical only if you had an exceptional amount of space available. It is probably best to take a carefully-calculated kit of spare tubes and parts, such as:

- 1-50,000 ohm, 50 watt resistor, with slider.
- 1 each-47 ohms, 220 ohms, 470 ohms, etc., (through 2.2 megohms) 2 watt resistors.
- 1 each-50, 100 and 500 pF and .001, .05 and .01 µF disc capacitors.
- 1 or 2-8 to 20 μF capacitor, rated for highest voltage any of your equipment uses.
- 1 spare for each final amplifier tube, and any other tube that runs in Class "C" or otherwise handles any appreciable power.
- 1 each-5U4 or 5R4 (or silicon replacement); 12AX7, 12AT7, or 12AU7; 6BQ7, 6BK7 or 6BZ7; 6AU6 or 6BA6; 6BE6 and 6AQ5 (or the 12 volt or octal equivalents).

SUB-MINIATURE SOLID STATE

TV CAMERA

FOR CLOSED CIRCUIT OR AMATEUR TV

THE VANGUARD 501 is a completely automatic closed circuit television camera capable of transmitting sharp, clear, live pictures to one or more TV sets of your choice via a low-cost antenna cable (RG-59U) up to a distance of 1000 ft without the need for accessories or modifications on the TV sets. The range can be extended indefinitely by using line amplifiers at repeated intervals or by using radio transmitters where regulations permit.

There are hundreds of practical uses in business, home, school, etc. for any purpose that requires you or anyone chosen to observe anything taking place anywhere the camera is placed. Designed for continuous unattended operation, the all-transistor circuitry of the 501 consumes only 7 watts of power.

SPECIFICATIONS:

- Measures 23/4" x 4" x 7" (excluding lens and connectors).
- Weighs 31/2 lbs.
- Operates on 100-130 volts 50 or 60 cycles, 7 watts.
- Tested at 10° to 125° F.
- Advanced circuitry utilizing 35 semi-conductors most of which are silicon.
- Field effect input circuit for minimum video noise.
- Resolution guaranteed to exceed standards set by 525 line TV receivers.
- RF output 30,000 microvolts adjustable for channels 2 to 6.
- Video output 1.5V p-p composite with standard negative sync (random interlace).
- Viewable pictures obtainable with illumination as low as 1 ft. candle.
- Vidicon controlled light compensation; 150/1.
- Adjustable iris on lens enables use in bright sunlight.
- New long life, sub-miniature vidicon with spectral response similar to Type 7735A.
- Electronically regulated power supply and thermally compensated circuits eliminate change in picture quality when line voltage and temperature fluctuate.
- All parts guaranteed for I year (except for open filament on vidicon or breakage).
- Fast, low-cost service always available from our factory in Hollis, N.Y.

Pre-set adjustable controls include the following: Video gain, video compensation, pedestal level, target voltage, beam voltage, beam alignment, electrical focus, horizontal frequency, horizontal size, vertical frequency, vertical size, vertical linearity, modulation and RF frequency output.

Send your order direct to our factory

VANGUARD LABS

196-23 Jamaica Ave. Dept. S Hollis, N.Y. 11423

This list will repair, at least temporarily, about 95% of the things that are likely to go wrong with communications gear. It should be modified to include any uncommon tube types or otherwise critical parts your particular equipment uses, but interchangeability should be stressed. For instance, the 12AT7, 12AU7 and 12AX7 all have the same pin connections, and will replace not only each other, but 12DW7, 12AZ7 and quite a few others as well in a pinch. Likewise, resistor and capacitor values are rarely so critical that those listed will not handle any replacement problem.

Shelter: Assuming there is no building at the operating site and you have to operate from a tent or a vehicle, check out the lay of the land before setting up, and take advantage of any features of the terrain that will help with the problems of heat and cold plus wind. As a general rule, "even in summer, hilltops are breezy and" cool at best and can get downright horrible in winter. It is therefore best to arrange for minimum wind, and for that to blow across the gear toward the operators. Since it is necessary to have something to cook on, or at least to heat water for coffee, a stove or heater should be chosen, but to serve primarily to heat the temporary "shack", with cooking capabilities strictly secondary. A kerosene heater, although smelly if not operated properly, seems to do better than the gasoline variety, and presents less of a fire hazard. In summer, mosquitoes and other "critters" become a problem, and all lighting should use the yellow bug-repellent type of bulb. On lower ground, assume that it is going to rain, and set up accordingly so you won't end up in six inches or more of water.

Food: Keep it simple is the word here. Coffee and soft drinks and/or 807's will be the most-consumed items, with not too much solid food consumed. A big batch of stew, chili, or reasonably solid soup prepared in advance, backed up by sandwich materials, is by far the easiest to handle. Frozen foods usually turn out to be a disappointment, since they thaw out before being used and just don't taste right—or conversely, if it's cold enough to keep them frozen, then it's almost impossible to heat properly. Who can operate on half-frozen stuff?

Don't forget's: It is highly frustrating to get all set to operate, and then discover that all but one crystal has been left home, or there are neither speaker nor phones

for the receiver, or no feedline for the antenna, etc., etc. To avoid this, a list should be made up in minute detail of everything that is to make the trip. For example, don't just list "transceiver"; instead list individually the transceiver, power supply, cable to connect them, mike, key, speaker, etc., etc., to be checked off one by one when the gear is loaded. Start the list well in advance and add anything the minute you think of it. Also save your lists from one outing to the next. Items which are usually forgotten are: log and pencils, clock, rotor control box, toilet paper, cooking and eating utensils, small parts of anything which must be dis-assembled.

Miscellaneous: You might think you have picked the most remote place in the world, but if you drove there, so will someone else before your operation is over. I have yet to operate without having visitors, friendly or otherwise, and even the casual ones will usually ask what you're doing. This is the time for the good old public relations pitch, explaining that you are testing your capabilities of providing disaster communications, which you are doing whether you planned it that way or not. This approach is good even in the face of some TVI complaints. However, if you get the "pure ungarbled word" that you are operating on private property, getting into the State Police radios, or some such thing -don't argue or try to make adjustments to the gear. Just apologize, pack up quickly, and leave. Finally, the most important advice of all: Portable operation is meant (like any other hamming) to be fun. Although a fairly business-like approach has been detailed here, it is like waxing the skis, checking over the fishing tackle, or filling the SCUBA tanks. In other words, a little foresight will mean just that much more enjoyment later on.

NEW! IMPROVED! SOLID STATE FREQUENCY CONVERTERS

Priced from only \$14.95 to \$39.95

OVER 5000 FREQUENCY COMBINATIONS FROM .45 MC TO 475 MC AVAILABLE FROM STOCK.

MANY NEW MODELS TO CHOOSE FROM OFFERING A TOTAL OF THE FOLLOWING: Crystal control, variable tuning, UHF epitaxial transistors, FET transistors, noise figures as low as 2.0 db, full wave varactor diode transistor protection, sensitivity better than 2/10 microvolt, fully shielded oscillators and band-pass filters to eliminate spurious frequencies, zener diode voltage regulation, 6 to 12 volts positive or negative ground, slug tuned coils, double tuned R.F. stages, tuned mixer stages, wide band I.F. amplifiers. All this plus the highest quality components carefully assembled, tested, and guaranteed.

We have exactly what you want at a lower price and better quality than you can obtain elsewhere. See our new multiple oscillator converters for monitoring two or more frequencies simultaneously!

24-hour special delivery service available on many models.

Send for your free 1967 converter catalog.

Practical Tips on Building Transistor Transmitters

Want to experiment with transistor transmitters? This article gives you the practical information you need.

From recent articles in the ham magazines and on-the-air conversations, it is obvious that interest in transistor transmitters is high. The thrill of working a station on the opposite coast with nothing but batteries for power is hard to beat. Many hams would like to build a solid state rig but shy away when confronted with pages and pages of formulas. I don't know very many good formulas so I'll pass along a few helpful hints and circuits, gleaned from hours of old-fashioned cut-and-try.

Test equipment

Before starting on a transmitter, a simple wave meter to indicate how much rf and at what frequency is in order. A helpful gadget for looking at rf in VFO and low power amplifiers is shown in Fig. 1. The probe end of the shield is not grounded to the gear under test. This unit can be constructed in an evening or so and calibrated with a signal generator. Its calibration is affected slightly by metal tables, etc., so when in use, make it a rule to set it on the type of material that you originally calibrated it on.

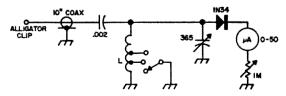

Fig. 1. Simple 3-30 MHz wavemeter-tuned detector useful for checking low power oscillators and amplifiers. L is 30 turns number 20 16 turns per inch, tapped at 14 and 5 turns from cold end.

If you have to purchase a meter, an imported S meter works fine and is pretty easy on the pocketbook. When coupled to a small pickup antenna, window screen, or SWR meter pickup, the wavemeter doubles as a field strength meter for on-the-air checks.

VFO's

VFO and VFO Mixer articles are numerous so we won't go into that. In fact, a stable transistor VFO is probably the easiest part of a solid state rig to build. It is worth mentioning, however, that for an all-band rig, a mixer type setup is easier in the long run. When you consider stability, break in, and calibration, it beats the oscillator-doubler-tripler business hands down.

Power amplifiers

Getting the drive from the VFO up to a useful level to drive a final on more than one band can be a pretty frustrating experience. The class C amplifier works very well with a bare minimum of parts and requires no keying, as the drive determines collector current. Fig. 2 illustrates two common emitter amplifiers. Fig. 2A uses capacitive input coupling, and 2B uses link coupling. An emitter stabilizing resistor can be placed in the emitter lead (bypassed, of course) if you have lots of drive. My experience has been that more output can be realized from a stage by omitting the emitter resistor and using a healthy enough

^{*}QST. September 1964. McKinley. "A Power Saving Conversion VFO."

transistor to hold up under the full output

of the preceding stages.

The tank circuit is the big hitch in a transistor power amplifier. Trying to use tapped coils for a multi-band rig is a little impractical. You wind up with a cabinet full of band switches and Miniductors, not to mention burned fingers and strained eyes trying for the best impedance match. Fig. 3 shows an interstage tank circuit using an Ami-Tron toroid that is fairly easy to build and works, too. This approach combines good Q, power transfer, and impedance matching, all in one neat little package. If you're a miniaturization nut, the toroid will fit in with your schemes nicely, as it is relatively unaffected by nearby components. The large Ami-Tron "E" core is used. Two or three turns will suffice for the links. The number of turns for the links are a compromise for all band operation. If the best impedance match is used for the highest band where operation is intended, the circuit will tend to provide equal output on the lower frequencies. Transistor gain dribbles off at higher frequencies so we shoot for the best match here. A single section broadcast capacitor works well for the tank capacitor and is available for 98c or so from many mail order houses. With 365 pF it is possible to cover two bands on the same tap so be sure to check output frequency with the handy wavemeter.

Output tank

The same arrangement can be used for output circuits with good results. Slight variations will improve the versatility. First, the use of a large tank capacitor will help maintain a decent Q. A double (700 pF) BC variable works nicely with just a few turns on the toroid. Link coupling can be used to the antenna or closer match can be obtained using a sort of sliding tap with capacitors as shown in Fig. 4. Loading up with three knobs is only one step above plug in coils as far as conveniences goes, so a differential capacitor is recommended for CIA and C1B. Since not everybody has one of these things nor the inclination to buy one, you can manufacture one from two identical stators bolted face to face on the same base plate with a common rotor. A close look at some old bolt-together type capacitors might reveal manufacturing provisions for this type of arrangement. (Now you know what all those extra holes in the ceramic are for.) If all else fails-two capacitors can be ganged to achieve the same

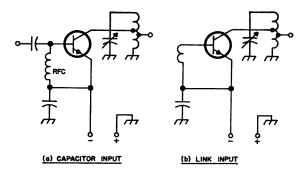

Fig. 2. Class amplifiers. Both are common emitter amplifiers.

effect. The idea being to have CIA decrease with a corresponding increase in C1A and vice versa.

What transistors?

One look at a transistor handbook and the dazzling array of a couple thousand types is almost enough to make you throw in the towel right there. Several articles have been written on choosing a suitable type for rf work so I won't elaborate (too much). The best low power (VFO, follower, etc.) type I've run across is a small NPN found on garden variety 3 by 5 surplus IBM cards at three cards for a dollar. A whole fistful of these for a dollar is an outstanding buy -especially with inflation upon us. If you go for higher power (say you want to light a No. 47 pilot lamp), I'd suggest the RCA 2N3053. These will stand 5 watts cw with a small clip-on heat sink for quite a while. I can't say how long because the originals in my rig are still there. Two in parallel will put a pretty healthy signal on the air and they're cheap—99c at last count.

Circuits and Construction

All the rules for regulation tube transmitters as far as shielding-layout, etc., apply to transistor rigs as well. They do have a few quirks, though, that we must consider. A common ground connection is a must because of low impedances involved. Along

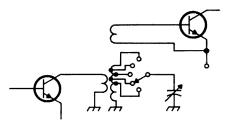

Fig. 3. Toroid tank coil and matching circuit. The links are one or two turns on the toroid. Tuned winding data is supplied with the toroid.

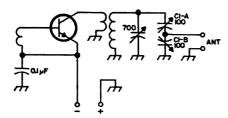

Fig. 4. Final amplifier using a toroidal tank coil and a versatile collector and antenna matching scheme.

this same line, use large bypass and decoupling capacitors. .1 μ F is not too big. Most power transistors have the collector connected to the case so it is a good idea to check this before you go to all the trouble of installing your heat sink on the chassis.

Designing around a positive chassis is a good idea. That way you can use NPN transistors and ground one side of your tank circuits. High gain NPN rf transistors seem to be easier to come by than PNP's.

Power supplies

Whether you use batteries or the AC line is up to you. I prefer batteries for their good regulation and portability. Since buying dry cells gets a little old after a while, for a rig over 5 watts, a couple of cheap car batteries and a charger make a good setup for home use, though a little unsightly. A trip to your local Honda dealer will produce some small plastic cased motorcycle batteries that will perch nicely behind your rig in a small poly tray, the latter being filched from your ever-patient, ever-sighing XYL. A 2 ampere-hour 6-volt size costs around \$4.00 and is good for many hours of operation with a 10 watt cw rig.

I hope the foregoing tips will make it easier for those interested to build a workable transistor rig. See you on 20 with your peanut whistles!

K0CIF

The Drano Finish

One of the nicest finishes that the home constructor can put on an aluminum chassis or panel is an etched finish. Normally this is done in a lye bath, but a much simpler approach uses materials which are normally available in the average household. Lye can be purchased in many grocery and hardware stores, but because it is dangerous, most people don't want to keep it in their homes. On the other hand, Drano is found in most kitchens and will provide the same results as the lye bath.

To etch the surface of an aluminum chassis or panel, the item to be etched must be absolutely clean. This may be accomplished by removing all the oil, greasy fingerprints and dirt with lacquer thinner, followed by a bath in hot, soapy water. Be sure to rinse the aluminum well in hot running water after cleaning; any traces of lacquer thinner or detergent which remain will result in an unevenly etched piece.

A large enameled pan or plastic mixing bowl is required for the actual etching process; the etching solution will attack most other materials. Be sure to select a container that is large enough so that the item to be etched may be completely submersed in the solution. To prepare the etchant, mix approximately two tablespoons of Drano with each quart of water required to fill the container. Use the hottest water that is available from your kitchen tap; the hotter the solution, the faster it will work.

To determine how long the aluminum should be left in the solution, a small sample should be etched before the chassis or panel is tried. This is because the required etching time is dependent upon many variables, including the type and hardness of the aluminum, the temperature of the solution, and the mineral content of the water. In some areas where the water is extremely hard, it may be necessary to use distilled water to obtain an evenly etched surface.

When the etching time has been determined, place the chassis in the solution and wait the required amount of time; make sure that it is completely submersed in the solution. Do not put your hands in the solution when it is time to remove the chassis, use tongs or rubber gloves. This type of solution is quite strong and will result in severe burns where it touches the skin. After the item is removed from the etching solution, thoroughly rinse it off in hot running water. The resultant finish is pleasing to the eye, mar resistant and long lasting.

. . . Jim Fisk W1DTY

A Phase-Locked UHF Microwave Oscillator

Philip Moldofsky K30JK Michael Paolini Jerrold Electronics Corp. Philadelphia, Pa.

Even if you don't expect to build this stable oscillator, you'll likely find the description of it interesting. It provides stability within 1 Hz at even 6.25 GHz.

The solid-state oscillator described below provides up to two watts output with rockstable frequency control from approximately 400 to 900 MHz and can be tuned for second harmonics up to approximately 1800 MHz with as much as 500 mW out. The power and the phase-locked frequency stability on both fundamental and second harmonic frequencies are well suited to a receiver local oscillator (requireing only milliwatts), an oscillator in a frequency multiplier chain, or a UHF or microwave transmitter.

By appropriate switching, the oscillator may be freerun or phase-locked to an external reference oscillator. There is also provision for an external discriminator, so that AFC may be substituted for phase-locking (APC). For simplest construction and operation, the oscillator can be run without either method of automatic frequency control, and this one-transistor, freerunning oscillator will drift less than 30 KHz (at about 600 MHz) in a fairly constant room temperature. Under AFC the frequency will be held

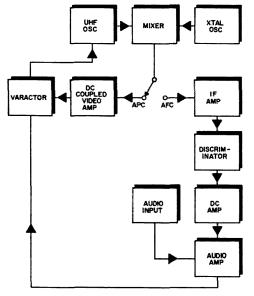

Fig. 1. Block diagram of the oscillator with various means of frequency control.

constant while the signal may be FM voice deviated. In the phase-locked mode, the oscillator can be used as a receiver local oscillator or as a CW transmitter, and the UHF output is locked *precisely* on a crystal harmonic. The phase-locked 400 to 900 MHz signal will be not even one hertz away from the chosen harmonic of your reference crystal frequency.

Circuit

The schematic of Fig. 2 shows the voltage regulating, current limiting power supply and the phase-lock circuitry consisting of the mixer, the video amplifier, and the varactor.

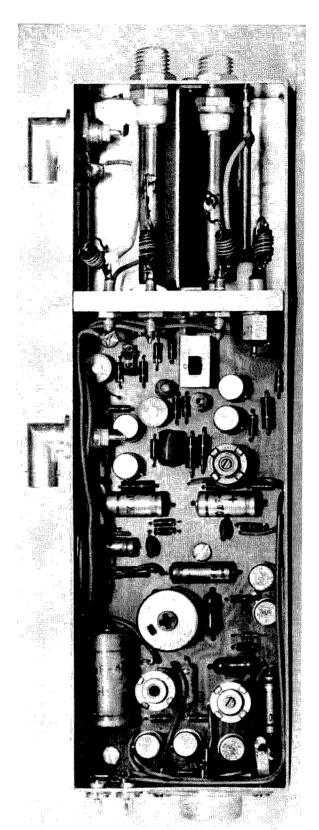

Power required is 25 to 35 Vdc, unregulated, typically at 175 to 300 mA. Also required are regulated +18 Vdc and -18Vdc at approximately 75 mA. The power section of Fig. 2 will provide regulated collector voltage for Q7 from the 25-35 V unregulated and offers an adjustable current limiter. When not oscillating, Q7 will draw damagingly heavy current, so the current limiter is a necessity. The 25-35 V is applied to the collector of Q1 and the regulated output voltage is taken from the emitter through a fixed drop, R3. Now, a variation in the output voltage will unbalance the differential amplifier consisting of Q5 and Q6, applying a restoring voltage to the base of Q3. This is built up through Q3 and Q2 and applied to the base of Q1, turning it further on or off, as required by the original output voltage variation. If output voltage increases, Q1 is turned slightly further off, thus dropping the output. A decrease in output voltage turns Q1 further on, decreasing the drop across it, and bringing up the output. Thus, regulated dc is applied to the collector of Q7, the oscillator. The base voltage is held by zener CR3 at 0.7 V. (The transistor may be damaged if the base is at more than 1 V.)

The current limiter consists of O4, which

senses the current being drawn by looking at the voltage drop across R3. The emitter-base voltage depends on the amount of current flowing through R3, so as more current flows, Q4 brings the base of Q3 closer to the output voltage. At a current level set by R4, Q4 will go to saturation and clamp the base of Q3 at close to the output voltage, so that no higher current can be drawn through Q1. R5 assures that even with no resistance from R4 between the emitter and base of Q4, the current will be limited to about 500 mA.

The dotted lines of Fig 2 indicate the contents of and feedthroughs to the tuned cavities. The collector and the base are tuned in twin 50Ω cavities which have the dimensions given in Fig. 4. O7 is a 2N4040 or a 2N4041, the 4040 being a double transistor in one case. With the 2N4040, up to two watts may be obtained on the fundamental frequencies from about 400-900 MHz and the cavities may be tuned to put out up to about 500 mW on second harmonics. Using the 2N4041, these power outputs are approximately halved. The circuit is the same for either transistor, so the choice is dependent only on cost and power desired. The output is taken from a coupling loop in the collector cavity. If the load into which the oscillator is working is highly non-linear, such as a varactor or a step diode, it may be necessary to provide a 2 dB attenuator at the output. Although this cuts output power by about 1/3, it does provide some isolation, which may make the oscillator easier to bring on when working into this special type of load. The 2 dB attenuator is made of three resistors, as shown in Fig. 2, and placed near the output BNC connector in the collector cavity. Ordinarily, when feeding into an antenna or working into a receiver circuit or any other load that is not highly non-linear, the attenuator is not needed.

The circuitry described above is all that is required for a freerunning oscillator. For frequency control, either AFC or APC may be used; Fig. 2 gives a complete schematic of the APC, or phase-locking, circuit. For AFC, refer to block diagram Fig. 1. The blocks supplied for AFC by the circuits of Fig. 2 are UHF OSC, MIXER, DC AMP, and VARACTOR. The external IF AMP and DISCRIMINATOR may be connected between TP2 and TP1 with the switch in the TP position; TP2 is then the mixer output and TP1 the dc-coupled video amplifier input.

UHF-microwave phase-locked oscillator.

Phase-locking is accomplished in the following way. A pickup wire from the collector cavity feeds a portion of the oscillator output into the mixer, to be mixed with the output of an external crystal reference

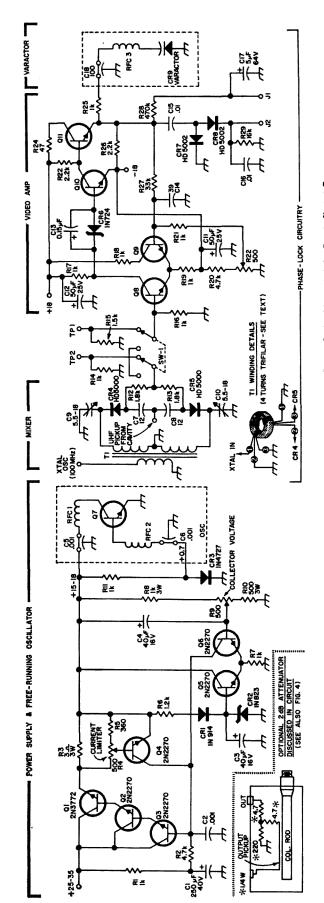

Fig. 2. Schematic of the power supply, UHF-microwave oscillator and APC loop. Dotted lines indicate feedthroughs to or parts located in the cavities. For cavity tuning elements, see Fig. 4. CR9 is a Motorola MV1864B, Q7 is a TRW 2N4040 or 4041, Q8-Q11 are 2N3866 (preferred) or 2N2270, 2N697 or 2N914. RFC1-3 are 6 turns #30 DNB on 1/4" phenolic form spaced to 3/8", and T1 is 4 turns #30 DNB trifilar wound on 1/8" to 1/4" diameter powdered iron core.

oscillator, fed in through T1. We should like the external crystal oscillator to operate at as high a frequency as possible, since the available phase-lock frequencies will differ by the crystal frequency. It will be easier to determine (by a method to follow) the phase-locked operating frequency if the possibilities are 100 MHz apart than if they are closely spaced and numerous. Also, with higher reference frequencies, we can lock on lower order harmonics and take advantage of their higher power. We used a crystal reference frequency of 125 MHz and recommend something on the order of 50-100 MHz. Of course, if you have in mind an exact phase-locking operating frequency, your crystal frequency must be a subharmonic (e.g., for 432 MHz you might use a 54 or 144 MHz crystal reference oscillator). Between ¼ and 1 watt are required from the reference oscillator on its fundamental frequency. When SW1 is in the phase-lock position, the mixer output is fed into a decoupled video amplifier. The operating bandwidth of this amplifier determines the lockin frequency range. For example, our amplifier went out to 10 MHz before it dropped off considerably, so the UHF oscillator tuning elements (including the internal capacitance of O7) could be tuned up to 10 MHz above or below lock-in frequency and the resulting error signal from the mixer would

Transistor	Collector	Voltages Base	Emitter
		23.2	22.6
Q1	25-35		
$\mathbf{Q2}$	25-35	23.8	23.2
$\mathbf{Q3}$	25-35	24.4	23.8
$\mathbf{Q4}$	24.4	25	25
$\mathbf{Q5}$	17	6.5	6
$\widetilde{\mathbf{Q}}6$	27	6.6	6
Q7	15-28	0.7	0
$\tilde{\mathbf{Q}}8$	6.3	0	-0.8
\mathbf{Q}_{9}	12	0	-0.8
$\overline{Q10}$	8	-17	18
Q11	1.7	8	8.5

Fig. 3. Typical transistor voltages. Measurements made with oscillator phase-locked and putting out 800 mW. Voltage on collector of 2N3772 (QI) was 28 V.

still pass through the video amplifier, reach the varactor, and continually keep the base

tuned to precisely nfxixi.

The choice of transistors Q8-Q11 depends on desired lock-in range. We used 2N3866's to achieve the 10 MHz usable amplifier bandwidth. However, if smaller lock-in ranges will be satisfactory, or if external AFC is used and the amplifier will pass only audio frequency deviation, 2N2270's, 2N697's, or 2N914's may be used with no other circuit changes. The amplifier, using 2N3866's, had 30 dB of voltage gain.

Now, with APC switched in at SW1, if the UHF output frequency starts to drift nfxta1 (phase-lock frequency), phase-lock loop sees this attempt to leave frequency as an attempt to go out of phase with the crystal oscillator signal. The mixer immediately puts out an ac error signal, which passes through the video amplifier and is applied to the varactor, keeping the UHF oscillator continually on the phase-lock frequency. For example, if the oscillator is tuned 3 MHz from lock-in frequency when it is turned on, the phase-lock loop senses that the signal is trying to go out of phase with the crystal oscillator at a 3 MHz rate, and retunes with the varactor immediately. While operating phase-locked, the output frequency can be no more than 1 Hz away from nfxta1. (If the crystal oscillator drifts, the phase-locked UHF output will, of course, follow the drift.)

Construction

The entire unit-power circuits, phaselock loop, and twin tuned cavities—was built in a copper box, 8½" x 2½" x 1 5/16". An etched circuit board made this tight construction possible, but etched circuitry is not absolutely necessary. The copper box serves two purposes; it provides a heat sink for Q7 and it forms four walls of the cavities. For best operation, a copper, brass, or aluminum block should be used as the combination heat sink-cavity wall. (See Fig. 4.) However, the four other walls of the cavity (and the other walls of the box) may be fabricated from copper clad board. Skin effect makes the wall thickness unimportant. If copper clad is used, all corner seams must be completely closed with solder. Such a box will not be as sturdy as one formed from 1/16" copper, but it may be more easily fashioned.

The power and phase-lock circuits may be housed in any chassis, but the dimensions of the tuned cavities must remain those of Fig. 4, with the possible exceptions noted in the following paragraph. Whatever type of construction is used (etched circuits, etc.), leads of the crystal oscillator input to the mixer and UHF pickup loop from the cavity should be short. This means placing the crystal oscillator input BNC connector and the components of the mixer (Fig. 2) close to the cavity.

For construction of the twin tuned cavities see Fig. 4. The two leads of Q7 shown are the collector and the base, which are soldered to the ends of their respective tuning rods. The two emitter leads should be soldered to the grounded dividing wall, with leads as short as possible (less than ½"). If sheet copper is used, a flange along the bottom of the dividing wall may be used for support. With copper clad board, the dividing wall may be soldered to the other walls on three sides. C_{*} and C_b are concentric cylindrical capacitors, with a range of about 1.5-7 pF.

However, it may be useful to obtain similar capacitors with larger ranges, which will be desirable to reach lower frequencies. When Ca and Cb are 1.5-7 pF, the oscillator can be tuned as low as about 600 MHz. To reach lower frequencies, the length of each cavity may be increased, along with the tuning rod in it. To fit the tuning rods to various cylindrical capacitors, the rod diameter may be varied slightly, but the cavity height and width must also be increased in proportion of maintain a 4:1 width-to-rod diameter ratio (e.g., 1¼": 5/16"). To tune as low as 400 MHz, the cavities should be stretched to hold rods 11 cm (4.3") long, and C_a and C_b should each have a range up to about 40 pF (which may be partly from the variable and partly from a fixed TCZ capacitor between points A and B and between C and D of Fig. 4). Concentric cylindrical capacitors are made by the Johanson Co., 400 Rockaway Valley Rd., Boonton, N. J. and by JFD Electronics Corp., Brooklyn, N. Y. 11219.

The varactor, located in the base cavity, is coupled to the base by the varactor's supporting rod and by an extra loop of insulated wire that may be brought closer to the base tuning rod. The varactor rod must be kept above ground, so the construction of Fig. 4 is used. The rod fits snuggly into a hole in a piece of Teflon, or other insulator, shaped as pictured. This, in turn, is mounted in the cavity wall. The hole for the copper rod is deeper than will be necessary to accomodate

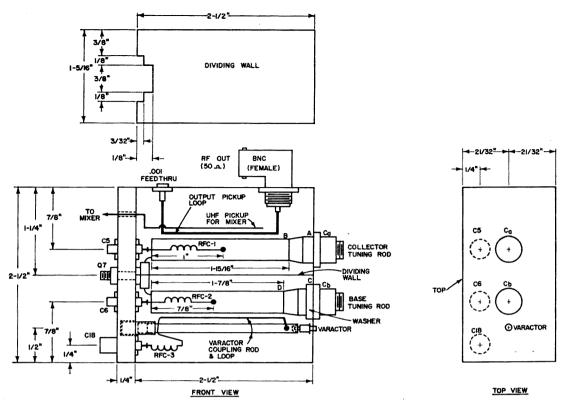

Fig. 4. Twin tuned cavities. See text for details on tuning capacitors Ca and Cb and for information on points A—D. The base and collector tuning rods are hollow brass tubing, 5/16" O.D. and the varactor rod is $\frac{1}{8}$ " diameter solid copper. The varactor coupling loop is insulated wire, about #26. The output coupling loop may be #18 insulated wire or a $\frac{1}{4}$ " brass strip, insulated by spaghetti, and the UHF pickup is #22 insulated wire.

it. This facilitates locking the varactor in position by pushing the rod into the Teflon, then backing out until the varactor is held between mounting holes in the rod and the opposite wall. A dab of solder on the rod, just outside the Teflon, now secures the varactor rod by preventing it from reentering the teflon.

The leads from the three chokes entering the cavities are soldered to the Teflon end of the varactor rod and to the collector and base rods at the places indicated in Fig 4. 50Ω BNC connectors are used for the crystal oscillator input to the circuit and the rf output from the cavity. This completes construction of the twin tuned cavities.

Tuning up and operation

The procedure for tuning up the oscillator consists of first checking out the power supply, then giving power to Q7 and adjusting the twin cavities to resonance. Once the oscillator is freerunning, the mixer is balanced, the video amplifier given power, and the varactor reverse bias set. Methods of determining when the oscillator is locked on frequency are discussed, as well as

methods of determining frequency of the UHF output.

When the power and freerunning oscillator circuits are completed, disconnect RFC1 and RFC2 from feedthrough capacitors C5 and C6. Caution: You must not apply power until Q7 has been taken out of the circuit by the removal of these two chokes. If the power supply is not working properly, Q7 could easily be burned out. (There should never be more than 1 V on the base or 28 V on the collector.) With Q7 thus disconnected, apply the 25-35 Vdc as in Fig. 2. Place SW1 in the TP position and do not yet apply the plus or minus 18 V. Measure voltages at the base and collector feedthroughs to the cavities. The collector voltage should be set with R9 to the highest voltage possible in the range 15-28 V. Now, the base should be at 0.7 V, held by zener CR3. With these two voltages correct, you can test and adjust the current limiter as follows. Choose a resistor to place between the collector voltage and ground so that about 600 mA would flow through it

$$(R = \frac{Vcol}{0.6}).$$

Place this resistor, which should have a rating of about 20 W, and a meter with a 1 A scale in series between collector voltage (at C5) and ground. The resistor is to protect the meter if the current limiter is not working. Now, you should be able to vary current through the meter with the current limiter pot, R4, from about 200 mA to 500 mA. R5 sets the 500 mA limit as explained under "Circuit". After checking that you have approximately the correct range of current limiting, set the pot for a reading of 350 mA on the meter. That should be ample current for normal operation. Disconnect the meter and its protection resistor. The current limiter must work to prevent Q7 from drawing damaging current when it is not oscillating.

With current limiter and collector and base voltages set correctly, and the phaselock switch in the TP position, reconnect the two chokes, thus applying power to Q7. Unload the cavity tuning rods by backing off the output pickup loop from the collector and the varactor coupling loop from the base. Neglecting output frequency for the moment, tune the collector and base capacitors (C. and C. in Fig. 4) for most power out as indicated on a power meter or a receiver connected to the output BNC connector. Now, move the output pickup loop closer to the collector rod for maximum output. If the Ca and Cb used had ranges up to 7-10 pF, the frequency of your initial you have determined, with the power meter or receiver, that the oscillator is freerunning, you are ready to tune to within the phase-lock frequency range and set up the phase-lock loop.

We tuned up using a Hewlett Packard Spectrum Analyzer, which allowed us to tune for frequency and peak power with no trouble. However, as this instrument is not commonly available, the following procedure may be used to determine output frequency. Of course, if a calibrated receiver is available, it may be used to determine frequency and the method below may be disregarded.

To complete the adjustment of the oscillator and phase-lock loop you will need a scope, an rf signal generator (such as Heathkit IG102) or a receiver, and a vom. The higher the frequency response of the scope, the easier it will be to locate your operating frequency, but a 5 MHz scope will be adequate. The method of frequency

determination when a calibrated receiver is unavailable consists of mixing the output with harmonics of several known frequencies from the signal generator and looking at the mixer output on a scope. A few signal generator frequencies will uniquely determine the oscillator output frequency. A more than adequate mixer circuit is the one in Fig. 2, consisting of T1, C7-10, CR4-5, and R12-14. It is advisable to build another mixer (besides the one you will use in the phase-lock loop) since, later, you will want to make frequency measurements while using the original mixer in the loop. Feed the signal generator into T1 ("Xtal Osc In" of Fig. 2) of this extra, test mixer and balance the mixer by adjusting C9 and C10 for O Vdc (±about .02 V) as read on a vom at TP2. Now, feed in the freerunning oscillator output between the two 12 pF capacitors, and look at mixer output (TP2) on the scope. If you are using a low frequency scope, a harmonic of the signal generator frequency will have to be relatively close to the oscillator frequency before you will see a sizeable trace on the scope. An example of frequency determination in this way follows. Tune the signal generator from, say, 100 to 150 MHz. Assuming that the freerunning oscillator is operating in roughly the range 600-750 MHz (for this example, say, 600 MHz), as you tune the generator you will see a mixer output on the scope as you approach each subharmonic of the oscillator frequency (here, 100, 120, and 150 MHz). When the mixer shows a sine output, tune the generator harmonic to zerobeat the oscillator (indicated by a straight line on the scope that becomes a sine wave upon tuning the signal generator either up or down slightly). Thus, if you find a zerobeat at 100 mc on the signal generator, you know the oscillator is operating at either 600, 700, 800, or 900 MHz. (With 7 pF maximum for C_a and C_b the cavities will not resonate below about 600 MHz. If your tuning capacitors have a higher range, the possible frequencies of this example would also include 400 and 500 MHz.) Now, to determine which of these harmonics is the actual operating frequency, tune the signal generator for a zerobeat at another frequency. In this example you would find one at 120 MHz. Since the only one of the 100 MHz harmonics that is also a harmonic of 120 MHz is 600 MHz, the operating frequency has been uniquely determined.

Now that you know the frequency of the

freerunning oscillator, you know which way and how far to tune the cavities to reach the desired harmonic of your crystal reference oscillator. Replace the signal generator with your crystal oscillator and use the above frequency determining method (or use a calibrated receiver) to tune first the base, then the collector slightly, alternating the tuning until the freerunning oscillator reaches the desired reference crystal harmonic. (Turning the capacitor screw in adds capacitance, lowering the frequency.) If it is desired to tune below about 600 MHz, the 12 pF fixed TCZ capacitor (Centralab) added to each cavity may be replaced with a TCN (negative temperature coefficient) or a positive temperature coefficient capacitor to compensate for any local heating effect you find. We did not find compensation necessary. In any case, keep the capacitor leads 1/16" or less. When the oscillator is freerunning at the desired harmonic of your reference oscillator, you are ready to adjust the phase-lock loop.

Begin by balancing the mixer. With all power to the circuits of Fig. 2 off and the crystal oscillator signal (1/4 to 1 W on its fundamental) into T1, adjust C9 and C10 for OVdc (± about .02 V) on a vom at TP2. Now, connect plus and minus 18 Vdc as indicated in Fig. 2. Adjust R22 for approximately 9 Vdc on the varactor. You can measure this directly between C18 and RFC3. The range available by adjusting R22 should be about 6-16 V. Place SW1 in the APC position and turn on the oscillator power. If the oscillator was freerunning near a lock-in frequency (nfxtal), it may come on phase-locked. If not, tune the base and collector until it does lock. To determine when the signal is phase-locked, place SW1 in the APC position and look at 12 on a vom. The mixer will have no measurable ac output throughout the lock-in range Therefore, (while locked, $nf_{xtal}-f_{osc}=0$). there will be no ac on the varactor and no de indication of varactor ac at J2. If the oscillator is phase-locked, you should be able to tune the base and the collector slightly (the collector will affect frequency less than the base) with the voltage at 12 remaining a constant minimum. At the same time, the voltage at J1 will vary as you tune. If you tune far enough to jump out of lock, the mixer will put out an ac error signal and the de indication at J2 will no longer remain constant as you tune, but will vary as you go farther from lock-in frequency. Using J1 and J2 in this way, you can determine when the oscillator is phase-locked.

To determine the extent of your lock-in range, tune the oscillator one way until it jumps out of lock. Use the previously discussed method of frequency determination to measure the output frequency at this point. Now, tune back through lock-in range until the oscillator reaches the other lock-in range limit and jumps out of lock. Measure this frequency. The difference between the two range limits is the total lock-in range. This range may be increased by (1) placing the varactor coupling loop closer to the base tuning rod, (2) lowering the dc reverse bias on the varactor with R22 (but do not go lower than about 6 V), or (3) placing the UHF pickup loop closer to the collector tuning rod.

One further method of increasing lock-in range is to improve the frequency response of the video amplifier. This may be accomplished by decreasing the feedback, thus increasing the gain, at high frequencies with a larger value of C14. With 2N3866's for Q8-Q11, and 39 pF for C14, the response was 6 dB down (or 2:1 in voltage) at 10 MHz. You may measure the frequency response of your amplifier by placing SW1 in the TP position, connecting a signal generator at TP1, and noting on a scope the amplifier output at the C18 end of R25 as the generator frequency is run up to about 10 MHz. Do not forget to take into account the frequency response of your scope.

When you have the desired lock-in range (probably plus or minus about a megacycle for CW operation, or 20-50 KHz if the video amplifier is to be used only for audio deviation in conjunction with an external AFC circuit), check the output on the power meter or receiver. Output power may be increased with larger collector voltages (but do not exceed 28 Vdc) and with tighter coupling of the output pickup loop to the collector. Also, make sure that the current limiter is not holding the power down. The current limiter should be set so that increasing the limit does not appreciably increase power output. Again, about 350 mA should be sufficient for normal operation.

With reasonable power out and the desired lock-in range, adjustment of the phase-locked oscillator is complete.

Application and results

As mentioned, the oscillator can be run in three modes-freerunning, phase-locked,

or AFC (with external circuity). This article is centered, as were our applications, around the phase-locked oscillator. We spoke, in "Circuit", about connecting an external if amplifier and a discriminator between TP1 and TP2 and using the dc coupled video amplifier, the oscillator, mixer, and varactor of Fig. 2 to accomplish AFC. (See Fig. 1.) Such a hook-up will allow FM voice deviation, Using any if frequency and any discriminator, tube or solid state. We also tried running the oscillator CW in the phase-locked mode as a CW transmitter, in a frequency multiplier, and as a receiver local oscillator.

Used as a phase-locked CW transmitter, we need a method of keying the oscillator. Not wishing to turn Q7 on and off, heating and cooling it, we keyed the rf output. By running the output through a cable with a BNC "T" connector in it, we can key the signal by keying a capacitor directly across the open "T". (See Fig. 5.) We found that a small 1.5-7 pF trimmer across the length of the BNC "T" resonated at about 600 MHz, placing an effective short across the output. This does not damage Q7 and we were able to tune the trimmer for a 30 dB difference (1000:1) in power output between "key up" and "key down". You may

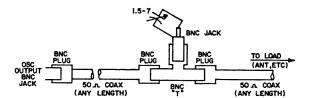

Fig. 5. Keying the oscillator by means of a tuned short across the output.

wish to try other methods of keying by shorting the output, such as a biased diode across the line, where the bias is keyed.

For those considering using the phase-locked oscillator as a receiver local oscillator, the S/N ratio is at least 70 dB at room temperature, for a 30 MHz bandwidth. The low noise aspect of the oscillator may interest radio astronomy enthusiasts, as the oscillator's second harmonic range includes the 1420 MHz hydrogen line and other atomic transition frequencies.

As the stable oscillator in a frequency multiplier, results were very good. Using a varactor multiplier we obtained 40 mW at 6.25 GHz (for a receiver local oscillator), taking about 300 mW from the phase-locked oscillator at 625 MHz. 625 MHz or 6.25 GHz, plus or minus not even 1 Hz, is something to think about.

Improving Tube-Socket Mounting Holes

Many retainer-ring-mounting tube sockets, such as the Amphenol Type S, have a number of notches on the edge. A tab on the edge of the mounting hole is supposed to project into one of these notches and prevent the socket from turning. This tab is commonly produced by a special socket punch which is quite expensive and not readily available. However, a hole produced by a conventional socket punch can be easily equipped with a tab, as shown in the photograph. From the material removed by the socketpunch, cut a piece 3/16 inch wide. Bevel the corners at one end so that it will fit the notches in the socket. Then fasten the piece to the underside of the chassis in the desired position with solder or epoxy cement. The tab will not interfere with the insertion of the retaining ring if the material is not overly thick.

Miniature-tube sockets using retaining rings require a flat in their mounting hole to prevent them from turning. This can be provided by a similar technique.

73 Tests the Eicocraft Code Oscillator

Here's the way the kit comes.

Eico is well known for its excellent electronic kits. I've built a number of them, including a stereo amplifier and 460 scope, and found them very satisfactory. Their new transceiver kit has received a lot of attention, and many hams have bought, built and used them.

A new Eico venture is a line of inexpensive kits for the hobbyist and experimenter. You'll see these kits in many electronics stores around the country. Among the Eicocraft kits are a fire alarm, intercom, burglar alarm, light flasher, siren, metronome, tremolo, audio power amplifier and ac power supply. They range in price from \$2.50 up, but not very far.

We received an Eicocraft code practice oscillator kit for test, and decided that the fairest test would be to have a person with no knowledge of electronics build the kit. Looking around the office for a suitable person, my eyes fell on the cute 18-year old girl who helps out in our subscription department. Judy agreed to try the kit, and she took it home to work on. I later heard that she'd had some problems, mostly with her husband, who wanted to build the kit,

but she finished the kit and it worked properly. Here are some of Judy's comments:

It wasn't too difficult to assemble the solid state electronic code oscillator. The instructions were quite easy to follow. Most parts were simple to identify and position, however, some were poorly labeled. With the use of both the diagrams and the assembly procedures, I eventually figured each one out.

Being quite unmechanically inclined, I found soldering to be the most difficult phase of the project. Just anybody certainly couldn't use a soldering iron without some basic instructions or some samples to practice on in order to avoid ruining the kit. The instruction sheet seemed to be lacking here.

I also had some problems with connections to the board from the speaker, key and battery since I didn't know how to strip wire. However, I did get the wire stripped after a few tries. Then I connected them all up and pushed the key. It worked!

And a few other notes. The parts were all of good quality and the oscillator worked fine and emitted a loud, clear tone. I'm sure that any budding electronics hobbyist would enjoy this kit and many of the others in the line.

100 Watts Out on Two with Compactrons

Here's a higher power final amplifier for two meters for all of you devoted KICLL followers.

This article just about completes our present series of low cost transmitters up to 100 watts output for six and two meters using today's tubes¹. Here is a transmitter for two meters which can put you well out of the 2E26-6146 class. Two 7894 Compactrons can put out 100 watts on two with high level modulation.

Considerations

Some interesting thoughts occurred on VHF transmitter design while working on

1. Six Meter Heterodyne VFO Transmitter, April 1965. Compactron Two Meter Transmitting Converter, September 1965.

4X250 Transmitter for Six and Two, April 1966. 50 Watts for 50 MHz for \$50, June 1966.

75 Watt Twoer Linear, July 1966. 80 Watts for 144 MHz for \$80, October 1966. All by K1CLL and all in 73, of course.

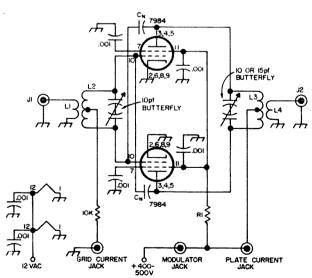

Fig. 1. Schematic of KICLL's Compactron push pull final amplifier for two meters.

this rig. Push pull has been used for VHF for well over 30 years, and ever since the pre-war days the general design for medium power tubes has centered around the double beam power tube with plates on the top and one glass bottle. Examples of WW2 tubes of this type of course are the 832 and 829. Since then a nice new series of this same type (5894, etc.) have come along. However, they are generally expensive and require a fancy socket. I have had the same one in a Johnson 6N2 for about 5 years and like it very well; perhaps because I keep the dc input strictly at 90 watts.

Today we have a new family of single ended tubes, real toughies, with ratings to 80 watts input on 175 MHz. These are the Compactron transmitting tubes with television priced 12 pin sockets that are intended for single ended use as detailed in several previous 73 articles¹. However, as you will see, when you do put them together in push pull, they go like two outboard motors on a racing hull.

Fig. 1 shows the schematic and Fig. 2 the pictorial layout of this amplifier using push pull 7894 beam power Compactrons. Each costs \$5.00 and the pair is rated at a de input of 162 watts in IMS (Intermittent Mobile Service). However, if you run this much power, expect to change tubes every now and then. If you don't want to change tubes every so often, then run 125 to 150 watts input to the two tubes.

Make sure that the two plate lines are the same length and that the grid lines are also equal in length. The neutralizing wires and tabs should then cross over each other and be similar as well.

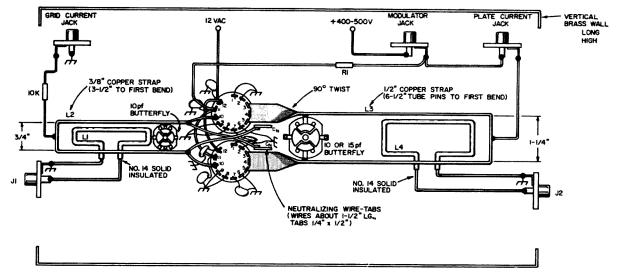

Fig. 2. Layout, coils and details of the two meter Compactron final. This drawing is one-third size.

Solder all eight cathode leads to the chassis, bypass the heater and screen leads with small flat disc capacitors, and you're ready to start "strapping." You can use coils for this type of circuit, but if you have room, lines are preferred. The push pull grid lines showed the usual improvement in length of inductance over the single grid type. Quite a nice tuned circuit was obtained which tuned up very well on two meters.

I obtained 7 mA of grid current through the 10-kilohm grid resistor, dropping to 4.5 mA when the screen and plate power was applied. Naturally some of the electrons which previously landed on the grid are now attracted to the screen and plate by their positive voltages. You should expect that the grid tuning will flatten out a little too. It will!

I tried both small and large size butterfly tuning capacitors on the plate lines, and both worked equally well. For arc-over security, I went back to the larger size.

The neutralization was easy after one or two tries. First I set up an elaborate little brass shield with large holes, subpanel insulator and nice long pins to carry the neutralizing wires through the shield from the grids to the plates. However, I had to go to the shortest possible heavy copper wire, about number 14, directly across the socket from grid one to plate two, etc. Putting 200 mA of plate current and no rf drive on the other tubes, the proper capacitance is easily found by watching for self oscillation with the plate and grid circuits tuned to 144 MHz. The ½ by ¼ inch tabs ended up about ¼ inch from the plate

lines. These tabs are really over the plate pins where they are soldered to the strap lines. Using insulated sticks, move the tabs nearer or further away from the plate lines and you will soon find the best place for both wires and tabs. The tabs, to be more explicit, are over the first ¼ inch of the plates lines. Half of each plate pin is bent over so it presents a flat surface to be soldered to the strap, and right over these points and about ¼ inch away are the neutralizing tabs. After the neutralization is completed, there should be no self-oscillation at any point in the 144 to 148 MHz range.

A plate dip of almost 70% was obtained with this amplifier. The pencil arc test with the plate dipped gets pretty hairy with 160 watts input; I would recommend that the pencil be taped onto a dry wooden stick and that the other hand be kept in the pocket. The arc is at least half an inch long. When this plate circuit is loaded it will brilliantly light a 100 watt bulb on two meters. You can use either loop coupling or direct to the 100 watt bulb porcelain socket for a dummy load. I tapped the socket onto the lines about 3¼ inches up from the cold end for maximum loading.

Baluns

Note that the input to the grid circuit has an unbalanced to balanced transformer in it. This is a perfectly legal type of balun and works quite well. Just for a check I inserted two chokes and capacitors in each grid to check the grid currents separately and with considerable satisfaction I found

them both to be exactly 6 mA. Note that inasmuch as I put in another 10 kilohm grid resistor, I now have 5 kilohms for the two grids. Actually the grid resistor turns out to be very non-critical so enough on that.

I tried coupling the exciter to the grids capacitively and by a link, but both methods provided practically identical results.

The final total grid current (both tubes) through the grid resistor was 7.3 mA with no high voltage on, and 6 mA with the high voltage applied. The screen voltage was 135 volts with the plate loaded to 100 watts dc input, and 80 volts with the plate dipped. In that condition fewer electrons land on the plate and more on the screen; probably a little better screen regulation is called for.

The grid bias voltage, developed by the rf drive across the grid resistor, was minus 58 volts with the high voltage turned off, and minus 44 volts with the high voltage on and 100 watts of load.

That's about it except for modulation. Theoretically we need 80 watts of audio to properly modulate the 160 watts dc input. Our standard modulator with a pair of 6L6GC tubes seems to be good for a maximum of 55 watts of audio, so either four 6L6's or a pair of 7894's will do the job. Also, two 807's or a pair of 1625's can put out up to 120 watts. You can see that we're skating near the point where everything gets quite a bit more costly, with 1200 volt power supplies, 811A modulators, big modulation transformers, etc. We'll see later about the cost of a good 80 to 100 watt modulator.

On the air

Hooking up the new double conversion superhet exciter, a commercial modulator, and a 500 volt supply which only gave about 125 watts input, I opened up with more power on two meters than I've had since my kilowatt days in 1949-1950. My little four element beam, two over two, about 10 feet over the roof had to do for now.

The first thing that happened was the number 48 bulb I was using for an rf output indicator nearly burned out. This is across the 50 ohm output antenna cable in series with a 1 to 5 pF capacitor. The trimmer was wide open, so I had to put in a 0.9 watt brown bead bulb which lit to about one half full brilliance. For now I had to lose that half watt. Shifting the B plus lead to the final down on the muli-match modulation transformer to accommodate the lower impedance of the push pull tubes, I listened in to my own voice on the "Amateur's Friend", the diode-amplifierpadded earphone system. It sounded real good so I tuned across the band. W1KI in Lynn, Massachusetts was chatting with a friend, so I switched on the exciter B plus, zeroed the exciter carrier in on the receiver pass band and had my first OSO with the push pull 120 watt rig. Don't forget, you can go to 160 watts if you have the modulator! Please note also that breaking in on two meters is a welcomed procedure.

A word about zeroing in without a BFO. I used to go to great lengths to heterodyne in with the BFO on, until one fine day I realized that the *if* pass band of a good receiver is fine for that purpose. Just leave the receiver tuned to the desired frequency, reduce the *if* and/or rf gain control, watch your S meter and zero in with only the exciter on. It works great; at least for AM phone.

All reports with this new rig were good. Stations that had heard my 50 watter (rf power out), noticed the increase in signal strength. It is a matter of individual taste just how much power you want to run. All those little decibels add up; beam, height, power, etc. This 100 watter gets you quite a way out of the 2E26-6146 class without jumping into the 1000-1200 volt region. There is quite a jump when you get into that class; things get real lethal, costs rise like mad, and size and weight jump too.

Hope to see you on two someday.

The Poor Man's Occasional Antenna

Here are some very cheap portable antennas that work well.

There are occasions when you want an antenna to use for a short time and you would like not to make a major investment. You'll even settle for something less than optimum. Such situations are representative of the sometimes mobileer, the vacationer in the woods or at the beach, the short time renter and the guy with limited real estate.

The sometimes mobileer

Many of us cringe at the idea of cannibalizing a good automobile. If you live ten minutes from work, mobiling has no attrac-

It's not very pretty, but this temporary antenna both stays on the car at 60 mph, and performs well.

tion as a daily operation. On the other hand you go for a vacation in the summer or a cross country trip for other reasons three or four times per year and you would like to have a mobile ham rig. The rest of the time you could care less.

There are assorted ways of bolting or strapping in or otherwise securing the rig inside the car without permanently marring anything, which we won't go into. But the major problem is the antenna. Any kind of permanent mount involves cutting holes in the body, purchasing an \$8 to \$12 mount and another \$8 to \$12 antenna and mounting same. It is easy to get \$25 tied up in a mobile antenna. Now for 23 cents apiece you can buy a couple of rubber suction cups and for less than \$4 you can buy a 9 foot fiber glass fishing pole blank. If you wrap the fishing pole with the proper amount of wire you can get it to resonate on any band and what's more it will radiate as well as any store bought antenna you might get. For over 30 years W7CSD has been hamming but never before mobile. We decided to give it a try. The photos show the lash up. The bottom is the remains of one section of a GI antenna upon which the fiber glass pole fits snugly with the help of a little bit of tape for shimming. We formed a hair pin of heavy wire around the bolt in the bottom suction cup bringing the ends together and pushing about 6 inches or so up into the metal rod. The top suction cup is "haywired" to the metal rod and a piece of cord is tied to the door

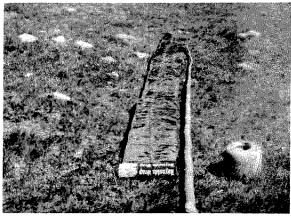

handle to make sure that nothing blows away. Likewise a cord or strap connects to the lower cup and runs under the door and ties to the door handle or window crank inside. Suction cups will hold by themselves up to 60 miles per hour but may come loose at higher speeds. Secured with cord in this way you can travel at any speed. The transmission line is two pieces of RG-59 in parallel which approximates 36 ohms and a good match for the whip. The line is only about 6 feet long anyway. The inner wires connected together clip on to the end of the winding on the pole and the shield clips to the chrome gutter. Windows may be cranked nearly shut or left open. Now about the pole itself. By the well known method of trial and error we decided to wind 16 feet of wire evenly spaced on the pole for a 20 meter quarter wave. We then ran a single turn between the whip and the gutter and placed the grid dipper coil thru the loop. It dipped beautifully at 21 MHz. So we had a 15 meter antenna. We soldered on at this point and wound a few more close spaced turns and dipped at 14 MHz. Actually we can use either tap and we resonate at 21.35 MHz on the top tap and 14.3 MHz on the bottom. We have worked all over the U. S. and one KP4 from W7 land on 15 and 20 meters with this arrangement. However the ignition noise while in motion is as yet an unsolved problem. The second whip wound for 40 meters works equally well and there is no ignition problem. This time we started out with 50 feet of wire and finally wound

the pole four times before achieving the desired frequency. We finally spaced considerably closer at the lower end of the whip. 60 feet evenly spaced would be pretty close. There is no question about getting a dip at the resonant point; it is very positive. Once completed the whole assembly can be installed or removed in a matter of minutes. We have received S9 reports from the Mexican border and the Canadian border both at the same time on 40 meters in the middle of the day. I doubt that a fancy store bought job could do any better.

The vacationer

There are those who go to a beach or mountain cabin and rely on Reddy Kilowatt to furnish energy. Of course the fiber glass whip would work here too. There is no question about it for the higher frequencies the

The makings of an inexpensive (18¢) vertical antenna.

old ground plane is the best bet if you are in a hurry. Of course there are those who still have the old screw together GI whip; they're ok too. Another stunt is to hang a quarter wave of wire between two trees, in a vertical position. A novel idea is to find a 16 foot 2 x 2 or even a 1 x 2 and pull out 16 feet of kitchen type aluminum foil and wrap it length ways around the lumber, clothes pole, sapling or whatever. Support it in a vertical position with some cord guys, string out 3 or 4 radials, connect hot wire to the foil and shield to the radials. With a transmission line of less than 6 feet between the xmtr and the ground plane a 16 foot vertical will work equally well on either 15 or 20 meters. Of course the SWR on 15 will not be good but who cares with 6 feet of line. Any pi net will load into it. We have worked the whole Pacific on 15 with this kind of a lash up. Last but not least is the trusty dipole for low frequencies. One sneaky way is to use some 300 ohm ribbon and run out the necessary 60 odd feet either side of center then clip out a section of one wire at the 33 foot distance and you have a 75-40 meter dipole which will also work very well on 15 meters. Here again let's do it the cheap way. Use 72 ohm ribbon. It looks awful small but actually it will stand about 10,000 volts without breaking down and you can even get away with feeding it a kW. Why mess with bulky and expensive co-ax? You can ground one side of ribbon in your pi network and it will work just as well as co-ax. How do we get it up? Climbing trees is for kids. If you're a kid ok. Otherwise do it some other way. A ball of binder twine is an excellent thing to have any way if you are camping or on a vacation. Throw a hammer

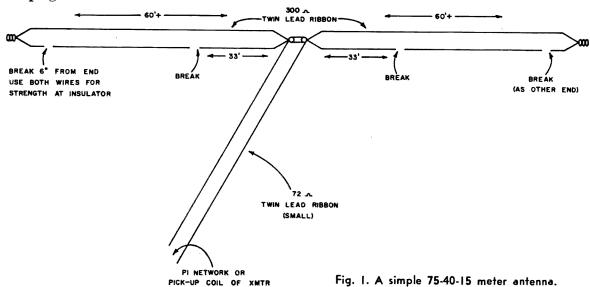

or other weight attached to the twine thru the branches of a tree or over a building and hoist the flat top. If you want to get way up, one method we have found that is very effective is to use a bow and arrow. The arrow will pull a light line over a pretty high limb. Binder twine is cheap enough to throw away when you move on. For a permanent support either for a flat top or to guy a ground plane binder twine loses its strength (and so does polyethylene cord).

The short time renter

The fiber glass whip will work well with a few radials strung out under it in a fixed location. Also the aluminum foil ground plane will last for quite a while if well wrapped. Aluminum pipe is quite reasonable and if you are on the second floor with a short transmission line to the ground plane the 20-15 idea will work here too. Of course an added loading coil would make the lower frequencies available. If the only way to go is up and you are permanently located, irrigation pipe comes in 40 foot lengths. A 4 inch one could easily be erected by two men and would be much cheaper than a tower. A lot of people are bothered by the insulating problems of the ground plane. This is not nearly as serious as one might think. In the first place a ground plane is current fed. The voltage at the feed point is very low. Dry wood makes an adequate insulator. Or better yet boil the end of the post, to support the ground plane, in para-

All of these low cost antennas will work and deliver a good signal. Try one.

Concerning Service on Ham Gear

It has been said that a chain is no stronger than its weakest link. Applying this logic to our ham business and taking all factors into consideration it seemed that customer service was one area that could be strengthened.

Johnny Q. Ham, in these days of sophisticated circuitry, simply hasn't the means to properly service or repair his gear and when it breaks down and needs attention, Johnny wants it done right and promptly, too. (Isn't that contest coming up next weekend?)

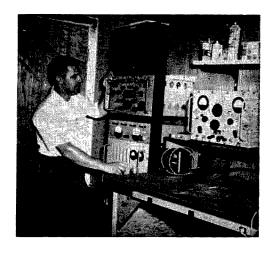

that contest coming up next weekend?)

Here at Harvard we have several strong points going for those who want prompt and correct treatment. We have extremely competent personnel each day and evening. We have the most advanced service facilities and we have a most comprehensive library of original manufacturer's service notes or instruction manuals all arranged to speed our work

and to insure *your* satisfaction.

The people working here are all practicing hams of long experience; they understand your problems and, more important, how to achieve the original manufacturers goals of performance. For example David Schilling has worked on and mothered literally hundreds of R388 and R390 receivers. Charles Branch has a kit of specially made tools for cleaning and restoring, like nothing we have ever seen before, and when Charley cleans up your A4 it will be just like new. Mervin McKee, whose specialty is sideband gear, can quickly null out the unwanted carrier and sideband and run a performance check on the overall gain of your SSB rig. Our newest lad Karl is particularly keen on Swan, National and Gonset's transistorized rigs, and on Collins S lines. All the boys are proficient. Dick Tassone loves mobile installations and he's constantly looking for that perfect noise free job.

Equipment wise we have solid state counters to 15 Gc and accurate to one part in 10⁸ per day (compare that with your BC221),

digital voltmeters, digital ohmeters and HP's 425 micro-micro amperemeter that will measure the energy of a mosquito's flight—that is if we knew enough to harness the critter. The techniques that each person employ are channelled to the kind of job you have for us. The best of Tektronix, G. R., HP and other specialized manufacturers are utilized to advantage.

So fellows if you want your gear serviced even though you bought it elsewhere and you want it done right and quickly drop us a line, or better yet send the piece along with a brief run down of the problem you're experiencing. Our charges are particularly modest considering our investment in facilities: Only \$5.50 per hour plus replacement costs. We're not in the service business but proper service is a necessary adjunct to our ham business.

For those who are considering purchasing new gear, isn't it some consolation to realize that these same service men and facilities are available to fulfill the terms of our warrantee? Very few pieces of new equipment ever need go back to the factory with the time consuming process of service and shipping two ways—causing you needless delays.

Prompt service is a proven factor at this company. Remember also that we sell all standard brands plus a full line of accessories. We're New England's only exclusive ham house.

Rewinding The Power Transformer

Many radio amateurs feel that the days of rewinding power transformers are long gone, and they may be right in this, but there are still two good reasons for "rolling your own", when it comes to certain cases. These are expense and the fact that transformers for certain voltages are hard to come by.

Actually a transformer is a simple device. It consists of a core, usually laminated iron or steel in a power transformer, and two or more windings of suitable wire wound on the core. The power capabilities are determined by the type of core material, the size of the core, and the diameter or gauge of wire used in the windings.

As an AC voltage is applied to the primary, (the input winding) it causes a magnetic field to expand around the core. That is, the core becomes magnetized. As the magnetic field expands, the magnetic lines of force cut across the secondary or output windings and induces a voltage across those windings. When the input voltage drops to zero as our 60 hertz current does 120 times per seconds, the magnetic field collapses, the lines of force once again cut across the secondary windings and a voltage of opposite polarity is set up across

т	able I

14	5.87
16	3.69
18	2.32
20	1.46
22	.918
24	.577
26	.363
28	.228

*Figured on 700 circular mills per ampere

those windings. The process is repeated again and again as long as an AC voltage exists across the primary winding.

The ratio of the number of turns of wire on the primary to the number of turns on the secondary will always determine the ratio of the voltages of the primary to the voltages of the secondary. This simply means that the following holds true.

$$\frac{\text{TURNS (primary)}}{\text{VOLTS (primary)}} = \frac{\text{TURNS (secondary)}}{\text{VOLTS (secondary)}}$$

Knowing these simple facts and that the power capabilities of a transformer do not change when we rewind it, we can proceed to rewind a transformer, for any special application. Step by step instructions are given.

1. First, figure your power, voltage, and current requirements. A 2½ volt transformer delivering 10 amperes will handle 2½ volts X 10 amperes or a total of 25 watts. This means that you must rewind a transformer capable of handling that much power. Most television transformers are designed to deliver 200 to 300 watts continuously, day after day, and will handle much more power in amateur applications.

2. Remove the shell covers from the transformer and identify the leads. Trace the wires back into the windings. Usually the filament winding for the rectifier tube is on the outside, then comes the 6.3 or 12.6 volt winding, then the high voltage winding and finally the primary or 117 volt winding. These can readily be identified by the color code in *most* transformers.

Green	6.3 or 12.6 volts
Yellow	5 volts
Black	117 volts
Red	High Voltage
Red and yellow	Center tap of HV

While this color code is not always used, a little work with the voltmeter will identify all the windings.

3. Remove the paper covering the first winding and count the turns of that winding. Divide the number of turns by the voltage of the winding. For a typical 5 volt winding, there may be 15 turns. This gives us 15 turns/5 volts or three turns per volt. This ratio of turns per volt will exist on every winding of the transformer.

4. Multiply the number of volts of your new winding by the number of turns per volt found in step #3. In my case I wanted 2½ volts for 866A rectifier turbes so I used 7½ turns on the winding. The size of the

wire needed to carry the current may be obtained from Table 1.

5. Now carefully (hal) remove all the windings you are not going to use. In my case I removed all but the primary. You may want to save the high voltage or a winding already in place. By saving a high voltage winding and adding a 28 volt winding we can build a nice transformer for surplus gear.

6. When you have removed the windings you no longer need, you can disassemble the core. Using a screwdriver, a light hammer, and a pair of pliers, force the E shaped pieces out of the core. Notice that there are about three E's facing one way and then three facing the other direction. The first few E's are hard to remove but the rest are easy. Also save the cardboard caps usually found on the ends of the winding area.

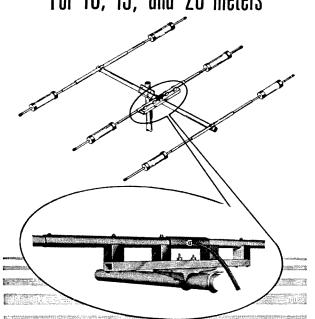

7. Now carefully put on the new winding. Formvar insulated wire is excellent for this and may be purchased at a local motor rewinding establishment or if you can't find it there, order it from Allied. Insulate between each layer of a winding and between the various windings. The easiest insulation I found to use was Scotch #33 tape but you can obtain paper for the same purpose. The winding may be put on by hand or if it is a high voltage winding with many turns, the core may be placed on a wooden block and chucked up in a lathe. Keep track of the number of turns or your face will be red later on. Do not forget your center-tap if you need one. A piece of well-insulated, flexible wire should be used and this solder connection should be taped well.

8. After the new windings are in place, tin the ends of the wire and attach flexible leads about twelve inches long. Now add a final layer or two of tape. In my case, since this winding would carry high voltage DC, I added several layers.

9. We're almost done! Reassemble the core, placing three E's one way and then three the opposite way. The last few will go in hard but use all of the core material. When this is completed, put on the shells and tighten the bolts that hold the transformer together. These will probably have to be retightened later as the transformer is used, until they are completely tight. If they are not tight, the transformer will buzz.

10. Install the transformer, use it, and think of all the bucks you saved by winding your own.

Revolutionary MATCHING The Classic 33 New from MOSLEY For 10, 15, and 20 meters

Yes, here it is from Mosley • • a Tri-Band Trap-Master beam (1 KW AM/CW and 2 KW P.E.P. SSB) featuring a NEW Mosley matching system, "Broad Band Matching" with coax fed balanced element for even more antenna efficiency and additional gain!

This 'Classic' New addition to the Trap-Master family of beams, incorporating the All-Metal encased traps made famous by the original and still extremely popular TA-33 beam, brings you: (1) A front-to-back of 20 db. or better on 15 and 20; 15 db. on 10 meters. (2) A gain of 8 db. over reference dipole or 10.1 compared to isotropic source. (3) A longer boom for even wider element spacing. (4) A SWR of 1.5/1 or better. (5) Priced to fit your budget.

The Drake L-4 Linear Amplifier

Jim Fisk WIDTY RFD 1, Box 138 Rindge, N. H. 03461

The new Drake L-4 linear amplifier has just about all the features you look for in a high power rf amplifier. Since this compact unit is rated for continuous duty, it will loaf along at 2000 watts PEP on single sideband, or a full gallon on CW, AM and RTTY in amateur service. The complete L-4 amplifier consists of an rf power unit and a solid state high voltage supply. There is a long connecting cable provided so the amplifier may be conveniently located at the operating position with the power supply tucked underneath out of the way.

The Drake L-4 may be driven to its full rated input on single sideband by any transmitter that has an output of 100 watts PEP. For full input on CW, AM and RTTY, the exciter must have an output power of 75 watts. For maximum efficiency, the 50 ohm input impedance of the amplifier is matched to the grounded grid power amplifier tubes

through a factory adjusted, broadband pi network. There is a separate network provided for each band and when peaked up it will cover the entire amateur band. To cover other frequencies in the 3.5–30 MHz spectrum, these circuits may be adjusted by the operator. This is especially helpful for those hams who handle a lot of traffic on the MARS frequencies. The necessary adjustment is very easy to make and requires only an SWR bridge; the instruction manual gives complete details and the entire procedure shouldn't take more than four or five minutes.

To ensure that the odd order distortion products are suppressed more than 35 dB, a slight amount of negative feedback is obtained in the L-4 by raising the grids above ground with 200 pF grid bypass capacitors. In addition, a very effective ALC circuit is included to prevent overdrive and

further reduce distortion. A small amount of rf energy is picked off the input and applied to a semiconductor diode which is normally reverse biased. The amount of reverse bias is controlled by the transmitting AGC threshold control, so the point where the rf is rectified may be precisely controlled by the operator. When the rf exceeds this reverse bias, the diode conducts and a negative voltage proportional to the rf signal applied to the grid appears at the ALC output connector. This signal may be used with the exciter through its external ALC input to control audio gain.

The power tubes are matched to the 50 ohm output by a conventional pi network. To maintain high Q and high efficiency, the tank coil is constructed of very large diameter tubing and completely silver plated. A portion of the rf output voltage is rectified and applied to the output meter through a sensitivity potentiometer. This little convenience is very helpful in obtaining maximum output from the amplifier since maximum output does not correspond exactly with plate current dip.

An internal antenna changeover relay is included in the amplifier to feed the antenna through to the receiver when receiving or when the power is turned off. To eliminate any diode noise which might be generated by the final tubes during receiving, they are completely cut off by applying 120 volts to their cathodes during receive. Since the tubes used in the final heat up to operating temperature in about three seconds, it only takes this amount of time from the completely off condition to the full rated input. This permits the L-4 and its power supply to remain off until it is required for communications (such as rare DX!). The fan used to cool the final is amazingly quiet and it's nearly impossible to tell that it's on without looking.

The two meters used to indicate plate current, grid current, plate voltage and relative output are of the taut-band type for maximum reliability and long life. This type of meter movement has virtually no friction, so the operator is assured of accuracy and repeatability. The upper meter always indicates final plate current, while the lower one may be switched to read grid current,

plate voltage or relative output.

Tuning up the Drake L-4 is a real snap and only takes a couple of seconds. Since the input stages are broadbanded and present an essentially flat 50 ohm load to the exciter, if the exciter is properly loaded into a 50 ohm transmission line with low SWR, turning on the L-4 has no effect on exciter tuning. After waiting three seconds for filament warmup, you can hit the switch, load the antenna, tune for a dip and call CQ. By checking your plate current and plate voltage, your final dc input may be easily calculated from the chart that the Drake Company provides in the instruction manual. This chart takes into account any fluctuations in line voltage (and therefore plate voltage) so that the full legal limit under various conditions may be easily calculated.

Although the high voltage power supply may be operated from either a 115 or 230 volt line, the 230 volt system is recommended for best supply regulation. In fact, when the L-4 arrives from the factory, it is connected for 230 volt operation. For 115 volt operation, it is only necessary to move a couple of the jumpers on terminal strips in the power supply and rf power unit. However, if a 115 volt circuit is all that is available, it must be fused for 30 amperes, the circuit conductors should not be less than number 10 and no other equipment should be operated from the circuit. Do not operate the L-4 from a standard 115 volt light circuit because the circuit conductors are not large enough to safely carry this load.

Most homes are equipped with 230 volt service for either an electric stove or a clothes dryer, so it's a relatively easy matter to have an electrician run a 230 volt line into your shack. Another solution, and one that I have used is to make a 230 volt extension cord using three conductor, number 14 house wire. When 230 volts is required, all you have to do is unplug the clothes dryer and plug in your extension. This is not the most convenient method in the world, but it does work temporarily until you can get an electrician to put another line in. Be sure to use large 230 volt plugs and sockets on the extension cord so no one can plug a 115 volt appliance into this line.

The proof of the pudding of any amplifier of course is in the operating, and this is where the Drake L-4 really shines. In amateur operation, probably the toughest conditions are those when a rare dx station is on and dozens of fellows are calling him. Obviously, the strongest signals will consistently work the rare ones first. Another good test is over difficult paths; from the east coast for example, propagation into the south Pacific area is usually open less than an hour each evening. Assuming a good location and a good antenna, the station that can consistently work into Tahiti, Samoa and Fiji from New England has a power amplifier that is really putting out. The L-4 performed magnificently in a recent dx test and added several new ones to the W1DTY countries list, including several from the elusive south Pacific. Running phone patches is another test where the Drake L-4 comes away with flying colors. On 20 meters in the evening it is difficult to find many spots that are void of QRM. Therefore, to run a phone patch, even locally, you have to have an outstanding signal. Here again the Drake does a very nice job, providing strong readable signals where lower power and lesser amplifiers just wouldn't do the job. For the amateur who works dx or otherwise must work over difficult paths, the Drake L-4 linear amplifier may be just the answer. It certainly has done an outstanding job for me.

The Carrier Again

W7CSD's article, "Amplitude Modulation vs. the Carrier," in the October 73 generated a lot of mail. Here's some further discussion of the topic.

OK fellas, I get the message. If you're a school teacher this happens at least once a week. So you take another approach. Let's start over again in the reverse order. Let's start out with what we know we have and see if we can find out what we started with. A mathematical example will put everything in focus.

Let's assume we have a 100 watt carrier, 100% sine wave tone modulated working into a 100 ohm load. Now I know they don't make 100 ohm coax but this is a handy figure for us to work with. First, we all can agree that this signal consists of a carrier and two sidebands. In this case (most of us will agree anyway) we have a 100 watt carrier and two 25 watt sidebands. Since a scope looks at voltage, let's reduce this to power in terms of voltage and resistance or E²R = P. Solving for E we find

 See W7CSD's article on page 82 in the October 73.

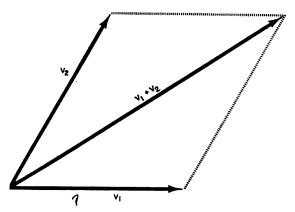

Fig. 1. Sum of two vectors. This is a parallelogram graphic solution.

that $E = \sqrt{RP}$. In the case of the carrier $E = \sqrt{100 \text{ x } 100}$ or $E_c = 100$ volts. Each sideband $E = \sqrt{25 \text{ x } 100}$ or $E_{sb} = 50$ volts. This will come as no surprise to most of us.

Now we know that we can represent any ac voltage as a vector (actually a rotating vector or more properly called a phasor). If we have several vectors to add we can add them up by several geometric means; the simplest is to form a parallel-ogram as shown in Fig. 1. The diagonal is the vector sum.

Now if all parts of the circuit are at the same frequency we can treat the vectors as though they were standing still and add them up and say this is what a meter will read if you put it in the circuit here. However if we are considering adding vectors at different frequencies we can only do so an instant at a time. In our AM signal (sine wave tone modulated) we have three components at three different frequencies. They must add up to the modulated wave. Let us use Ve, the carrier voltage, as a reference vector. Remember that it is rotating but we can treat it as if it were standing still if we use it as a reference. Then vectors of other voltages at other frequencies are rotating faster or slower than the reference. Now let's see what the vector sums are for several instants in time. At time T1 we find Ve in reference position, Vu, the upper sideband pointing to the left and rotating counterclockwise (by trigonometry counter clockwise is considered positive and the upper

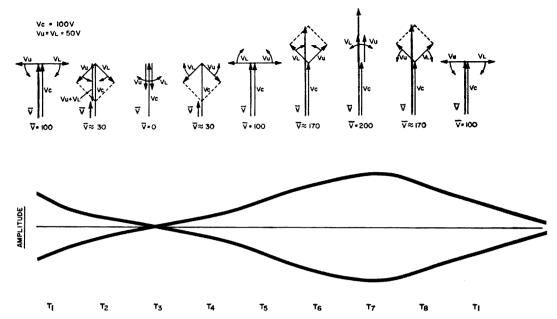

Fig. 2. Modulation envelope plotted from instantaneous amplitudes by vector addition. The color overprint gives the vector sum indicated by V with a short bar over it.

sideband is higher in frequency and therefore rotating faster than the carrier) and VL, the lower sideband is pointing to the right and rotating clockwise (slower than the carrier). The vector sum is the carrier itself or we are going thru the zero modulation point. 45° later at T₂ we see the resultant is a small fraction of the carrier and we are in the negative modulation area. At T₃ the sidebands completely cancel the carrier and we have 100% negative peak. At T₁ we have the same condition as T2. At T5 we have the same condition as at T₁. At T₆ the resultant is greater than the carrier and is in the positive modulation region. At T₇ all vectors add directly and we have twice the amplitude of the carrier.

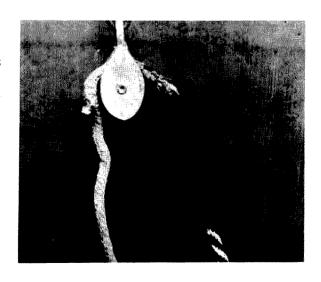

100% positive peak many other points in time could be taken. Thus we generate the well known AM envelope by vectorially adding the side bands and the carrier. Note, the carrier is there all the time. The question immediately arises. What happens if you over modulate? Now you cease to talk about two discrete sideband frequencies, upper and lower. You are now making a square-bottomed envelope and additional sidebands (splatter) are generated. What ever these additional sidebands may be they will make the vector sum of the carrier and all sidebands add up to zero on the negative peaks and the carrier will still be there.

. . . W7CSD

Replacing Halyards

Replacing halyards has always been a problem because a knot will not pass through the pulley hole. I have been using nylon ski rope which only costs several cents a foot and lasts for years. I found that when it had to be replaced I could cement the two pieces of rope together by using a small piece of Nylon twine between them. The small twine is inserted in the ends of the ropes and a match held underneath it until it becomes sticky. In a few minutes it will solidify and be secure. Now, by pulling on the old rope, the new one will come right on through the pulley.

Jim Kyle K5JKX 1236 NE 44th Oklahoma City, Okla.

A Simple Current Controller

Frequently the experimenting ham finds need of a device to control *current* in a circuit, rather than voltage. One example of such a need is in a RTTY local loop, where current should be maintained at 60 mA (for a Model 15) even though line voltage, and as a result the dc supply voltage available for the loop, may vary. Another example is the bleeder resistor of a power supply, which must always draw a minimum current but which is only wasting power if more than that minimum is drawn.

The conventional approach to this situation is to use a voltage much higher than desired across the load, and drop it through a high-valued resistor. For instance, RTTY circuits often use a 125-volt supply and a 2000-ohm resistor, so that 60 mA can flow under short-circuit load. Small voltage changes then result in little current change.

In the case of the bleeder resistor, the resistor value is merely figured so as to draw minimum permissible current with the minimum voltage expected. As voltage rises, so does bleeder current, but we don't worry too much about the wasted power.

However, because of the unusual characteristics of tetrode, pentode, and beampower tubes, it's simple to build a true constant-current generator, or controller, which can be set for any desired amount of current and will maintain current flow

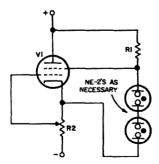

Fig. 1. A simple current controller.

very close to that value regardless of the voltage applied.

Some extra voltage is still needed to operate the tube, but it's usually much less than needed to assure reasonably-constant current under voltage variations, were the conventional resistor hookup employed.

The controller works because a tube with a screen grid will, if both screen and control grid voltages are fixed, maintain a constant current flow regardless of plate-to-cathode voltage (except at extremes of operating characteristics). Actually, the current isn't absolutely constant—but if, instead of holding control-grid voltage fixed, we obtain it by means of cathode bias so that the bias increases as plate current does, then the cathode current will remain virtually constant throughout the tube's operating range.

The circuit is shown in the schematic. No parts values are given because they will depend entirely on the individual application. The tube can be any screen-grid type which will pass the desired amount of current; in general, TV horizontal-output tubes seem to work best as their effective amplification is high. However, the 6V6 is also excellent.

The screen voltage should be chosen to allow the desired current to pass with the grid voltage placed about halfway between zero and cutoff. It should be regulated by a string of NE-2's or VR tubes as shown so that it won't vary with the current. R1 is simply a dropping resistor and should be chosen so that the NE-2's all light under operating conditions.

The value of R2 will determine the range of current control possible. Its maximum setting should be such that cutoff voltage for V1 will be developed by the minimum current desired. Then with the arm toward V1's cathode, current will increase, and with maximum resistance in the circuit, current will be at a minimum.

To see just how this works, let's plug in a few numbers. Let's assume we're using a 6V6 for VI, and are holding its screen voltage at 250 volts. Furthermore, we want to have 20 mA current flowing in the external circuit.

A look at the curves for the 6V6 shows that with a screen voltage of 250 volts, and the same voltage on the plate, a grid-to-cathode bias of 20 volts will allow 20 mA of current to flow. This 20 mA will develop the required 20 volts across a 1000-ohm cathode resistor, so we use a 1000-

ohm unit for R2 and bring the grid back to the lower end (with a larger pot, we set it for 1000 ohms between grid and cathode).

Now if the load should attempt to make current increase to say 25 mA, the grid bias voltage would also increase to 25, reducing current flow to about 9 mA. Of course, as the current flow dropped the grid bias would drop accordingly, so that as current passed 20 ma going down the grid bias would be back at our 20-volt starting point and the practical effect would be that the current never got a chance to change at all.

If the voltage applied to the current-control and load together were to increase so that there were 400 volts across the 6V6 instead of 250, the 20-volt bias would still hold current to 21 mA. However, 21 mA of current would increase bias to 21 volts, which would result in current dropping to about 18 mA, and as before it would stop before dropping so low. The stop this time wouldn't be right at 20 mA, but would occur at approximately 20.05 mA—which is fairly close control!

Should we want to deliberately increase the current from 20 to say 40 mA, the curves tell us that grid bias should be 13½ volts. Ohm's Law tells us that about 338 ohms is the size resistor needed to develop 13½ volts with 40 mA flowing, so that's the setting for R2.

Now an increase in load current from 40 to 60 mA would give us a bias increase to 20¼ volts, which would in turn reduce current to about 20 mA, and on the way down things would lock up at 40 mA where they started, just as before.

Thus, by making R2 adjustable, we can dial the amount of current we want to flow in the circuit, and the controller keeps that current constant.

Should supply voltage drop so low that the screen voltage of VI drops out of regulation, the gadget fails. This can be overcome by supplying the screen from a separate source, because plate voltage can be allowed to drop far below the screen value before the device stops working. However, in many applications the major problem is a change in current drawn by the load,

Used as a bleeder resistor, this circuit will draw only the amount of current it is designed to pull no matter how high the supply voltage goes (until VI blows up from overvoltage around 1500 volts or so!).

Second-hand 6L6's are cheaper than 25-watt resistors, and far cheaper than 100-watt bleeders. The wattage requirement in a bleeder comes primarily from the power thrown away by excess current at highest voltage; this hookup will let a single 6L6 bleed a 750-volt supply, without wasting any current either.

What's New for You?

This second of our monthly columns devoted to any topics of special interest to the technically-minded ham will be a bit short as the first announcement of the column didn't reach readers in time for them to submit items. We'll be looking for something from you in next month's 73.

This column is interested in short notes about new semiconductors, newly available surplus, technical nets, technical meetings, new records, comments about articles that have appeared in 73, notes about equipment and other topics. Please make your comments short and get them in to us early. The deadline for items for the next possible issue of 73 (April) is the 10th of February.

Paul Franson WA1CCH

Correction

The "Home Brew Rectifier" described on

page 52 of the November issue is wired for a negative output voltage rather than positive. If you wish to use this circuit for B+, reverse the diodes.

Attention Galaxy Owners

Owners of Galaxy 2000 Linears and Galaxy remote VFO's should write for service bulletin 6-1, which gives some useful information including the use of the remote VFO on RTTY. Write Owen L. Meyerson, Galaxy Electronics, 10 South 34th Street, Council Bluffs, Iowa 51504.

Correction

In the article by WIOOP in the September 73, "Add AGC to your receiver," the diodes in Fig. 2 on page 27 are reversed.

Correction to Correction

Sigh. The correction on page 113 in the December issue is wrong. The N-channel and P-channel FET's are reversed.

Equalizing AFSK Tones

Common methods of keying audio oscillators for AFSK lead to unequal mark and space amplitudes. This article describes a simple method to avoid this.

The common method of obtaining an audio frequency shift signal is to switch the tuning capacitance of an audio L-C oscillator, as shown in Fig. 1. The space frequency (2975 Hz) is formed by L-C1, while the lower mark frequency (2125 Hz) is formed by L-(C1+C2). While adding C2 lowers the frequency, it unfortunately lowers the circuit impedance which usually lowers the Mark output level. I say "usually", because it depends on the oscillator circuit and the circuit Q. This reduced mark output can cause distortion in the receiver TU, and lowers the mark S/N ratio.

A review of the literature shows that this mark-space amplitude difference is either neglected or equalized by a C or LC network in the oscillator output. I would like to propose a much simpler method of tone equalization.

The Twin City AFSK circuit was used as a typical oscillator for tests, with the keying circuit temporarily omitted (Fig. 2). The mark amplitude was measured at 3 dB below the space amplitude. Let's see what

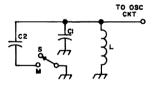

Fig. 1. The common method of obtaining an audio frequency shift for RTTY.

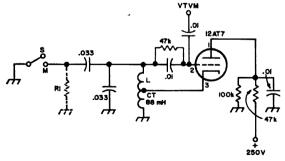

Fig. 2. Oscillator section of Twin City AFSK less keying diodes.

can be done about this.

Instead of thinking of the mark amplitude as being too low, let's consider the space amplitude to be too high, and look for an easy way to lower it. Adding resistor R₁ (Fig. 2) across the switch does the trick. The mark circuit (L-C₁C₂) is not affected, but the Space circuit now has its Q lowered by R₁ in series with C₂. As the value of R₁ is decreased from a very high value the space amplitude drops quickly, but the space frequency is almost unaffected, as shown in Fig. 3. For this particular circuit the tone amplitudes will be equal if R₁ is 125kΩ. The space frequency shift due to R₁C₂ is only 3½ Hz.

Now let's continue with the diode keying circuit of the Twin City circuit, Fig. 4. R. loads the space circuit through the keying diodes, D₁ and D₂. The circuit characteristics were first measured using silicon TV diodes

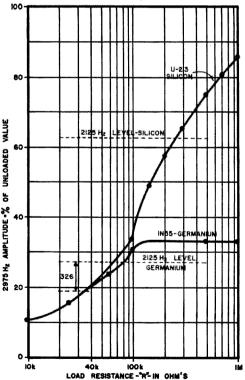

Fig. 3. Effect of tuned circuit loading an amplitude.

(Texas Instruments U-213) for D_1 and D_2 , with the results shown in Fig. 5. Note that the mark and space tones will be equal in amplitude if R_1 is $250k\Omega$.

Next germanium 1N35 diodes were tried. These are similar to the Twin City 1N54's, which I didn't have. Fig. 5 shows that the germanium diodes load the space circuit, due to their low back resistance. R_1 should be about $85k\Omega$ for equalization, but this will vary with the particular diodes used. (The voltage across the oscillator circuit is a bit high for 1N54's and 1N35's). If R_1 is $39k\Omega$ as shown in the Twin City circuit, the space amplitude will be about 3 dB below the mark, just the opposite of the usual situation.

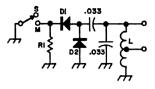

Fig. 4. Twin city keying circuit.

While the proper value of R₁ will vary with the circuit used, I believe an equalizing value can be found for almost any oscillator and keying circuit. Remember that equal mark-space percentages of modulation are the goal. If your speech amplifier is not flat, this system will permit the proper amplitude adjustments.

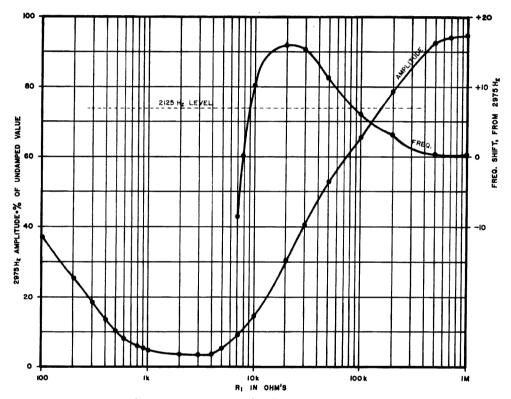

Fig. 5. Effects of diode loading on space amplitude.

Cutting Holes in Window Screens

When you bring a transmission line into the shack, many times the most obvious route goes right through a window screen. Much to the consternation of the XYL, many hams are apt to stick a screw driver into the screen and spread the strands a little bit. A neater method is to use a conventional chassis punch about a half inch in diameter. To prevent the strands from unraveling, several techniques may be used.

If the screen is brass or copper, the strands around the opening may be soldered together. For aluminum or plastic screens, a little bathtub caulk does a marvelous job. If care is taken in choosing the size of the chassis punch, the cable will fit snugly in the opening and no insects will get in. Furthermore, if the hole is placed near one of the corners, it may be patched up later with little notice. . . . Jim Fisk W1DTY

International Crystal SBX-9 Sideband Exciter

If you're one of those fellows who has been procrastinating about getting on VHF sideband, the new International Crystal 9 MHz sideband exciter is just what you're looking for. The high frequency addicts can read on too, because the SBX-9 is equally suitable for any of the ham bands below 30 MHz. Basically, this new exciter from International Crystal is a crystal controlled 9 MHz single sideband generator with selectable upper or lower sideband. It uses a very steep sided four crystal half lattice filter in conjunction with a 7360 balanced mixer to obtain a minimum of 45 dB carrer suppression with at least 40 dB suppression of the unwanted sideband.

In all, the SBX-9 uses four tubes to generate 0.5 volts of 9 MHz sideband energy across the 50 ohm load. In the input a high impedance dynamic or ceramic microphone is used to drive a 12AX7 audio amplifier; this audio signal is fed into one side of a 7360 balanced modulator. The control grid of the balanced modulator tube is fed by

the 9 MHz rf carrier which is generated by a 6BH6 crystal oscillator stage. The carrier is balanced out in the 7360 by the balance control which is connected to the tube's beam deflection plates. When the audio signal reaches the 7360, the balanced modulator becomes unbalanced at an audio rate and produces a double sideband suppressed carrier signal. This signal is fed into a crystal filter where the undesired sideband is suppressed and the desired sideband passes through to the grid of the 6BA6 rf amplifier. The desired sideband is selected by choosing the exact frequency of the 6BH6 crystal oscillator. Since the 2 kHz crystal filter is centered on 9000.00 kHz (9 MHz), the upper sideband will pass through the filter when a 8998.5 kHz crystal in used in the oscillator; conversely, the lower sideband will get through if a 9001.5 crystal is used. Because of the steep sides and narrow passband of the crystal lattic filter, the audio sideband outside the filter passband is suppressed some 50 dB. The 6BA6 rf amplifier is tuned to MHz and feeds the 50 ohm output through a link coupled to the plate tank.

There is a test switch provided on the front panel of the exciter which unbalances the balanced modulator and keys the push to talk relay. This is used where a carrier is necessary for adjustment of an external power amplifier or mixer. The internal push to talk relay has a number of contacts which are brought out to the accessory socket. These auxiliary contacts may be used for turning on external power amplifiers, switching antenna changeover relays and muting receivers and converters.

Since the SBX-9 has a fixed 9 MHz output, the front panel has a minimum number of controls. In fact, to put it on the air all you have to adjust are the carrier balance and audio gain controls. And, once the carrier balance is set, it requires very little further attention. A 100 microampere meter is connected across the plate circuit of the 6BA6 rf amplifier to measure the amount of carrier. All the operator has to do is

International Crystal SBA-50 50 MHz SSB Mixer-Linear Amplifier

turn the SBX-9 on, key the push to talk relay and adjust the balance control for minimum indication on the meter; then talk into the mike and adjust for proper audio gain as indicated on the meter. The complete adjustment takes only a couple of seconds and results in a minimum of 45 dB carrier sup-

The SBX-9 is designed primarily as an exciter for the SBX-50 50 MHz mixer-amplifier, but it may be used with homebrew mixers on other amateur bands by the proper selection of frequencies. The use of a 5 MHz VFO and suitable mixer-amplifier circuits for instance would provide single sideband on either 75 or 20 meter phone. Other frequencies may be added by the addition of appropriate crystal controlled mixer

The sideband signal from the SBX-9 is very clean on the scope and sounds very crisp and sharp. The high quality crystal filter and use of double tuned circuits results in high efficiency with maximum suppression of undesired signals. For the amateur who is interested in getting on sideband without going to a transceiver, particularly on the VHF bands, the International Crystal SBX-9 is an ideal choice.

The new International Crystal SBA-50 50 MHz single sideband mixer-linear amplifier was designed as a companion unit for the SBX-9 sideband exciter for operation on six meters. This dandy little transmitter takes the 9 MHz sideband output of the SBX-9, mixes it with a crystal controlled signal in the 41-45 MHz range and puts out 10 watts of single sideband single tone on six meters.

The circuitry of the SBA-50 is quite straightforward, starting out with the triode half of a 6U8 in a simple third overtone crystal oscillator circuit to provide the necessary output on 41 to 45 MHz. If VFO operation is designed, it may be connected to the SBA-50 through the accessory socket on the rear deck of the unit. However, one of the three crystal positions must be va-

cated and that switch position used when the transmitter is VFO controlled. The tetrode half of the 6U8 is operated as a VHF mixer. In this section of the 6U8 the 41 to 45 MHz signals from the crystal oscillator are heterodyned with the 9 MHz signal from the single sideband exciter. The resultant sum frequency at 50 to 54 MHz is selected by the tuned mixer plate circuit and inductively coupled to the grid circuit of the 12BY7 linear buffer amplifier. This six meter signal is further amplified by the 6360 linear power amplifier and link coupled from the power amplifier tank circuit to the 50 ohm coaxial output. This signal may be used for communications within the six meter band or used to drive a larger linear power amplifier.

You won't be able to put it down!

We should give fair warning to those who order this new book from the Radio Society of Great Britain. Once you pick it up, you won't be able to eat, sleep, talk or watch TV until you've read it all. It's a fascinating, densely-packed, 100-page book full of every imaginable practical circuit for ham radio. Hundreds of circuits and ideas are discussed, and each one is useful to hams. Here are the chapters: semiconductors, components and construction, receiver topics, oscillators, transmitter topics, audio and modulation, power supplies, aerials and electrical interference, troubleshooting and test equipment. Once you've digested this book thoroughly, you won't be able to build or modify any gear without consulting it.

The SBA-50 is very easy to use and it only takes a few moments to completely tune it up. Once the SBX-9 9 MHz exciter has been properly tuned up, it is a simple matter to tune up the SBA-50. The switchable meter circuit may be used to read any one of five different circuits within the amplifier; the oscillator grid, 9 MHz drive (mixer grid), buffer grid, power amplifier grid, and rf output. Except for the input and output circuits to the final power amplifier stage, all the circuits have been factroy adjusted so there is a minimum number of panel controls to worry about. Since most six meter operation is limited to 52 MHz and below, the circuits within the transmitter are broadbanded enough to require no further tuning. However, if operation from one end of the band to the other is required, it may necessitate tweaking up the circuits slightly when going from 50 to 54 MHz.

Adjustment of the final amplifier tuning controls is very straightforward; put the SBX-9 exciter in the test position, place the meter switch in the PA grid position and adjust the grid tuning control for maximum reading; then place the meter switch in the rf output position and adjust the plate tuning and loading controls for maximum rf power out. Once the audio gain control has been adjusted for the proper meter reading, you're ready for your first six meter single sideband QSO.

You won't find a great deal of six meter single sideband activity in some parts of the country, but with units like the SBX-9 and SBA-50, it shouldn't be too long before all the stations on 6 meters are using this more efficient mode found on the lower frequencies.

These two new units are ideally suited for the amateur who is interested in sideband communications on our VHF bands. Although this complete unit is designed for six meters, the resultant six meter signal may be heterodyned up to two meters, 220 or even 432 with a simple homebrew mixer circuit. These units are extremely well made, stable and put out a very clean and crisp signal. With the supports on the upswing, it won't be too long before there will be world wide openings on six meters. When the DX going gets rough, it has been proven that ssb is the mode to be using; the SBX-9 and SBA-50 provide an excellent base for an outstanding ssb signal on six meters.

...WIDTY

The National 200

Jim Fisk WIDTY RFD 1, Box 138 Rindge, N. H. 03461

When National came out with their new model 200 transceiver a few months ago at a lower cost than any other five band transceiver on the market, I just couldn't believe that it would perform as well as the more expensive models. But-after using it for several weeks in chasing DX, I find that they have done a superb job and performs right along with the best of them. The sensitivity is fine, the selectivity afforded by the steep-sided crystal filter is excellent, and the audio reports, if I am to believe the fellows on the other end, have all been good. Reports of, "tremendous audio quality," "really sounds good," and "very clean and crisp," have been normal reports during the time I have had the 200 on the air.

In the National 200 the final amplifier pi network and the driver tuning circuits also double as the rf circuits for the receiver. The VFO and carrier oscillator are common to both transmitter and receiver and the first if stage in the receiver also serves as a low level amplifier in the transmitter. The use of common crystal filter and rf input components results in a sensitive and relatively image-free receiver and highly efficient ssb transmitter. Sideband switching is automatic with lower sideband on 40 and 80, and upper sideband on 20, 15 and 10 meters.

The front end of the receiver starts out with a 6BZ6 rf amplifier, followed by a 12BE6 mixer, the 5.2 MHz crystal filter, two 12BA6 if stages at 5.2 MHz, a 12AX7 AM detector, product detector and first audio, and finally, a 6AQ5 audio power stage. The AGC voltage is derived from the second if stage, run through a semiconductor diode voltage doubler to get it up to the proper level, and then applied to the

first if and rf stages.

The 8.7 to 9.3 MHz high frequency mixing signal from the VFO is premixed in a 6GH8 stage with a crystal controlled signal on 40, 15 and 10 meters so only one stage of conversion is required in the receiver itself. On 80 and 20, the VFO signal is mixed directly with the incoming rf signal to obtain the 5.2 MHz if. This procedure somewhat simplifies things and eliminates many problems with spurious responses and birdies that might appear in the receiver tuning ranges.

The tube lineup in the transmitter begins with a 6GH8 microphone preamp, then

to a 6GH8 speech amplifier and solid state balanced modulator where it is mixed with the 5.203 MHz signal from the 12BA6 carrier oscillator. The sidebands at the output of the balanced modulator are fed into a 12BA6 transmitting if amplifier and then into the crystal lattice filter. The sideband output of the filter goes through another 12BA6 for further amplification, then to a 6JD6 transmitting mixer where it is mixed with the VFO and carrier oscillator signal available from the 6GH8 premixer. A 6GK6 driver and two 6JB6's in the final complete the layout of the 200 watt ssb transmitter. The excellent sideband qualities are a direct result of the very steep sided crystal lattice filter and the use of double tuned circuits in the transmitting if stages.

The National 200 incorporates a very sensitive automatic level control (ALC) circuit in the final. This circuit makes use of the fact that when the control grids of the power amplifier tubes are overdriven on voice peaks, the resultant positive voltage on the grid causes grid current to flow. This current in turn causes a negative voltage change in the bias network; the resulting audio signal on the bias circuit is capacitively coupled to a voltage doubler for rectification and fed back to the first if stage to control the audio gain. When the final amplifier is overdriven, the gain of the first if stage is reduced, resulting in less driving signal at the fnal. The ALC voltage cannot discharge through the voltage doubling circuit, so the resultant action is a fast attack and slow release. The circuit is designed to provide an automatic leveling control for 10-dB variations in the audio signal. This makes the setting of the microphone gain quite noncritical and changes in the voice level or large background noises are controlled without distortion. When the National 200 is used with a linear amplifier, there is provision for using an external ALC signal from the linear to control the audio stages of the 200.

The variable frequency oscillator used in the National 200 uses a straightforward grounded-cathode Hartley oscillator. minimize the effects of warmup drift and to insure long term frequency stability, all the frequency determining components in the VFO have been carefully selected. To further insure the frequency stability of the unit, the output is taken from the screen grid of the oscillator tube. After a 30minute warmup, the stability seems to be very good. Variations in line voltage have

only a very slight effect; not enough to require retuning the station you're working. After an initial 5 minute warmup, the unit drifted about 1000 Hz over the next 25 minutes; after this 30 minute period the drift was insignificant.

In addition to operation on single sideband, the 200 may be used on CW or even AM. A simple adjustment on the back sets the carrier insertion for CW and AM. Once this control has been set for one band, it may be left alone. The mode switch on the front panel automatically suppresses this control for ssb operation but permits full carrier insertion on AM and CW. Actually, when this pot is switched into the circuit in the AM and CW modes, it is used to upset the balance of the diode modulator. In addition, for AM or CW, the bias is removed from the 12BA6 transmitting if stage, providing full carrier insertion of 60 to 300 mA.

This transceiver is designed to load into a 40 to 60 ohm unbalanced load. When the load is within these limits, it loads up very nicely and quite quickly with the three controls required. In this respect, the National 200 is similar to many other transceivers on the market—peak the exciter, load the power amplifier and tune for a dip. Since the receiver uses the transmitter tuned circuits in its input, when the transmitter is tuned up, the receiver is also matched to the transmission line. In the transmit mode, the meter reads final amplifier cathode current; in the receive mode it functions as an S-meter.

The National 200 may be used either in a fixed station from the 115 volt line with the AC-200 power supply, or mobile with a power supply that furnishes all the necessary voltages. To aid the mobileers, National has thoughtfully included a mobile mount in the package with the 200. This mount is a U-shaped bracket that may be clamped under the dash of your car; the transceiver fits into the bracket and is held in place with a couple of large knurled thumb nuts. To remove the unit for fixed station operation, all you have to do is disconnect the antenna and power plug and remove the thumb nuts.

All in all, the National 200 transceiver seems like a very good investment for those of you who are shopping around for a good all band transceiver. It is compact, lightweight, easy to use, and best of all, it works well. It's not often that you get all these attributes in one package!

. . . W1DTY

A Universal Code Monitor

Want a monitor that requires no external battery, can be used with each and every cathode-keyed transmitter, and is small enough to be mounted to your key?

By taking advantage of the voltage drop across silicon diodes in the forward biased condition, a convenient source of regulated voltage to power a transistorized code monitor is attained.

Referring to Fig. 1, the heart of the universal code monitor is shown. Placing three silicon diodes in the ground lead to the transmitter from the key accomplishes two objectives: One, with the key open, any possibility of high voltage being present across the transistor is eliminated; and two, with the key closed, a voltage drop of approximately 2.1 volts is obtained for powering the monitor. (0.7 volts per silicon diode in the forward biased condition) Watch the polarity of those diodes! If they are placed in the wrong direction, it will be readily apparent as no current will flow.

Three diodes have been shown, but the actual number will vary depending upon the overall volume level required. More diodes-more voltage, and hence louder the volume produced. With 2.1 volts to power either of the two transistor circuits shown, the volume is sufficient for the average ham shack. Selection of the diodes will depend upon the current drawn by the keyed stages of your transmitter. To make it universal, 500 mA diodes should be used. The monitor may then be used with any transmitter drawing from 10 to 300 mA. In this application, the PIV rating of the diodes is not important, so relatively inexpensive diodes may be used.

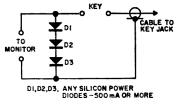

Fig. 1. The voltage drop across three forward biased silicon diodes is about 2.1 V, sufficient for simple oscillators as shown in Figs. 2 and 3. The diodes are shown for a cathode keyed transmitter.

Fig. 2 shows a transistorized circuit which may be used. This circuit draws approximately 2.5 mA at the 2.1 volt level and gives sufficient volume even under noisy conditions in the ham shack. If an output transformer other than that specified is used, some juggling of C₁ and C₂ may be necessary to obtain oscillations.

Got a portable radio around that is no longer used? If so, the parts to build an audio oscillator may be laying there waiting to be used.

Fig. 3 shows an oscillator circuit which may be easily built from parts normally encountered in the small portable radio. The driver transformer may have four leads on the secondary. If it does, simply solder the two middle ones together for the center tap. Use caution in removing the transformer from the portable radio's printed circuit board as excessive heat can open the leads internally.

The speaker can be the one in the portable, or may be one with an impedance anywhere from 3.2 ohms to 100 ohms. The transistor can be the preamp, driver, or one of the output transistors in the audio stages of the portable.

This oscillator does not give the volume that the one in Fig. 2 does, but is sufficient in a quiet ham shack. Of course, more diodes at the key would produce higher voltage and higher output. With the values shown, this oscillator draws only microamps at 2.1 volts. If lower values of base bias resistors are used, the current drain will go up correspondingly. Changing the values of the capacitors across the transformer will change the tone, but with the values shown,

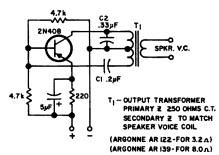

Fig. 2. A simple, loud monitor. It draws about 2.5 ma at 2.1 V.

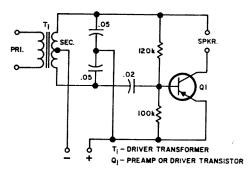

Fig. 3. This monitor can be made from parts from a junked transistor radio.

a pleasing tone is readily attained with most driver transformers. The capacitors shown are generally present in the radio.

Due to the relatively small number of components and their small physical size, the whole monitor may be built directly on the key through suitable means. Changing from one transmitter to another presents no problems as that encountered with monitors which require a pickup loop or external power source. Simply plug your key into the next transmitter.

If you want some additional code practice, just connect a 11/2 volt battery to the monitor and you're on your way.

(Editor's Ramblings from page 4)

issue, we've been printed by Hildreth Press of Bristol, Connecticut, a division of the Printing Corporation of American. We've endured bad service, indifference, poor quality and improperly-wrapped and late magazines. We have been shooting for a mailing date of the 13th of the month preceding the date on the cover, but haven't hit anywhere near it. For instance, the December issue was mailed in early December instead of November 14. Attempts to improve the situation have been fairly fruitless, and we decided that the only solution was to change printers.

Our new printer is Morton Printing Company in Pontiac, Illinois a central location that should please hams on the West Coast. We're hoping that they will be far more satisfactory in a number of ways, and expect the 73's to be mailed on time. Of course, I have no way of knowing as I write this editorial (on December 14) whether the magazines were mailed on time. Changing printers is rough at best, and lack of cooperation from the printer you're leaving can hold things up quite a bit.

FIBERGLASS QUAD ARMS

First time ever offered at this unbelievable price. More than 2 years in R. & D. These full length mandrel processed reinforced Fiberglass arms are practically indestructible in application. Cross arms are reinforced at base and wire intercept points. Give your Quad a professional look with high reliability.

13 ft. Long. These Quad Arms can be purchased separately at \$6.50 each.

These rigid die cast mounts are poured from a special aluminum alloy bullion with low deterioration and fatigue factor. 2 in. hub diameter. Special "V" angle will handle any diameter quad arm from 1 in. to 1% in. O.D. Comes complete with all necessary hardware. Separately, \$6.95 each

BOOM TO MAST "T"

Die cast to true fit a 2 in, O.D. boom to a $1\frac{1}{2}$ in. O.D. steel mast such as popular T. V. mast. Complete with hardware.

Separately, \$4.95 each

Gus; Part 20

In the last episode I was back at Aldabra Island for the second time, but business was not as brisk as before since I had over 7,800 QSOs the first time there a few months before. There must be a new crop of DXERS every few years because I QSO many fellows right now who tell me they still need Aldabra. The second stay there I had something like 3,500 QSO the few days I was there, most of them saying, "Thanks for the new one!" I guess most of these boys must have been on the second and third lavers the first time there. I wonder how many were on the fourth and fifth layers? I guess every three or four years any place becomes rare if there is no activity from it during that time. So many fellows keep saying they need this or that even after thousands of QSOs and at times right after I had left a place too.

This second trip to Aldabra was for the purpose of bringing supplies, loading up copra and hauling back "live turtles" Mahe. This was a pretty fair size ship this trip. After loading up dried fish, copra, exchanging a few island workers we were ready to finish loading up the boat from stem to stern with those big turtles, live ones at that. They were loaded on the ship by a small crane and placed upon the deck upside down and covered with wet coconut and palm branches. These branches were to be kept wet all the way back to the Seychelles to keep the turtles from drying out. It was quite a mess trying to walk around the deck with all these turtles everywhere. Usually you ended up on tip-toeing between them, but at times you had to walk smack on top of them. This did no damage to them since they were tough old critters and it

took a lot more than walking on them to kill them. Anchors were lifted and we were again on our way to VQ9 land. The mood of the sea was not very good, because the South East monsoon was in full swing and the date indicated we were in about the middle of the monsoon. You just connot expect a nice smooth sea at this time of the year in that portion of the Indian Ocean. The weather was like it was supposed to be-rough seas. My /MM operating position was up on the "Poop Deck" right beside the big wheel, and strapped down good and solid. We were about 25 or 30 foot above the water and this more or less multiplied the tossing of the ship. The chair was fastened down good and solid too, or I would have slid all over that little room. Radio conditions were excellent. They always seem to be when you are at sea. I still think the world's best operating place is in the middle of the ocean with that beautiful ground all around you. I think its even better than the QTH of W5VA and W3CRA. I bet if a fellow had a full kW and a five element beam on a ship out in the middle of the ocean "no one" would trample on him. He would always be on the top of the pile. After being out from Aldabra only 2 days I was up in the little poop deck operating away about 5AM and out the corner of my eye watching the young fellow at the wheel who in turn were watching the big compass keeping the ship on course many sea birds were all around the ship, a few porpuses were parading pass the ship taking their morning's tour I suppose, and even a few schools of flying fish were seen taking off when the ship caused them ORM. Plenty of activity is always seen at that early hour when at sea, we were getting our second cup of that strong coffee from the galley boy and we were just taking it easy as no big pile was on hand on the bands. I was just enjoying myself and I think the fellow at the wheel was doing the same. We two and one fellow in the engine room, I think was all that were up out of the sack, everyone else was sound asleep waiting for the six bell signal for them to get up. I then noticed the fellow at the wheel was doing a little straining at the wheel which was very unusual because generally he could could turn the wheel with two fingers and never any strain whatsoever. About five minutes later I noticed he was really trying to pull the wheel with both hands and it was not moving at all. I pulled off the phones and asked him what was wrong? He

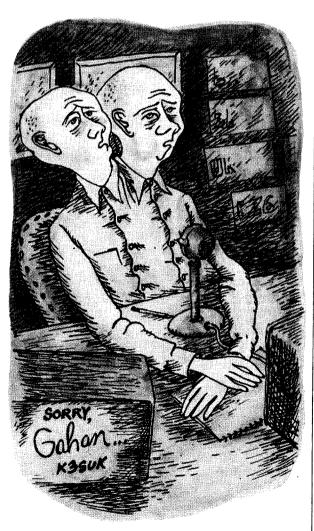

said there was some trouble with the wheel or rudder. After he had pushed and pulled on the wheel a few minutes it suddenly started "free wheeling" and thats when he said. "we have some bad trouble somewhere". Down he went to wake up the captain and the ship turned broadside to the wind, the engines were turned off and all sails let down. Seems like everyone on the ship suddenly woke up when the ship turned broadside to the wind and began to really toss and pitch. The captain and all the rest of us went to the rear of the ship to look at the rudder, there it was turned up at about a 45 degree angle and right when we all were looking, it dropped off the ship and sank to the bottom of the Indian Ocean. We were at least 200 miles from the nearest island and a lot's further than that from Mahe, drifting with the wind and currents. The gang was worried to say the least. We just drifted a few hours while the situation was discussed, the captain did not seem to disturbed about the situation as much as the ship's crew. They were concerned. As for myself I took the attitude that it was not my ship and if it sank it was no money out of my pocket. The radio gear was insured, so Ack said, so nothing to worry about there, and I had a good life insurance policy so I figured the one to really worry was my insurance company not me! I decided since I had no intention of diving overboard to try to find the rudder that I would just head back to the poop-deck and do a little hamming and get my mind off the situation. The little putt-putt was again cranked up and a CQ sent, I had quite a few good ragchews with the boys and did mention to some of them about our rudder being missing, Some said, "That tough Gus". Others said "Sure hope you all find it." (Who was going to dive to the bottom of that Indian Ocean?-NOT ME!), Some W5 said, "Well I'll be doggoned if that ain't tuff, Ole Buddy" Someone asked me over the air what was I going to do, and I said "nothing". Had a FB OSO with some EP2 station in Tehrein and told him the whole story, he said he was going to do what he could for us! He was very interested in the whole story, our exact QTH and all other details about the whole thing. The captain wanted me to try to get in touch with Harvey Brain-VQ9HB in Mahe so he could get a message to the ships owner-Mr. Teemoulgee, the big merchant in the Seychelles. I told him I would have to get the message to Harvey thru (5Z4GT Leny or George 5Z4AQ) that even-

ing. That evening about 6 PM local time I did get a OSO with George 5Z4AO, and he said "My God" when I told him of our troubles without a rudder, broadside the high winds, water slashing over all the decks and everyone starting to worry-except the Captain and me. I am one of these fellows who thinks when his number is up, it's up, Or else I am crazy enough to just not worry about something that was out of my control, and something I could not do anything about. I gave George all the details, our QTH, directions of the winds, number of people on board, etc. I found out later that since George was working for Kenya Radio that all this info was put out thru the Cable and Wireless and broadcast world-wide for all the news services to pick up. It was picked up in Orangeburg, South Carolina and broadcast probably by all three of the broadcasting stations here. My wife heard this broadcast and this started the ball rolling, all the children was called home, our local Baptist minster was called to our house, lots of weeping and carrying on around the Browning house. Someone suggested contacting Ack, this was done and Ack assured them that we were not in any immediate trouble (I like that word immediate!). So they quit worrying (I think) and things calmed down at home. Things did not calm down on the ship, oh not by a long ways. Everyone was discussing our troubles and making suggestions. The captain had his own opinion as to what he was going to do. He had decided to use a cabin door to replace the rudder. The largest cabin door was removed and large rope attached to it, no hinging was possible, it was going to have to be controlled by pulling ropes. A big "V" groove was sawed in the rear portion of the boat, this was where the Cabin door was supposed to fit in so it could be swung back and forth. Now you picture trying to mount this thing on the rear of the ship and remember those large waves and high winds trying to keep you from doing this. Now Buddy I could see that we had problems and I mean big ones. This cabin door was supposed to be held in place by those 34 inch ropes being tightened by pulling in from both sides to hold it in the "V" center of the groove. Everybody grabbed their ropes and they edged the cabin door towards that "V" groove, bang, a big wave hit it, it went sailing off across the water, back it was pulled by the ropes. The men were excited, and a number of them were almost pulled overboard.

sneaked down into that little "V" groove again, it gets pretty close this time, and away it goes again, a few little cuss words here and there, a little hair pulling, more discussions and try again, this kept up hour after hour. The Captain showing no signs of discouragement. Everyone else agreed that this task was absolutely impossible and asked me to get a message to Mombassa for a towing ship to be summoned so we could get back to Mahe! We took a position "shot" the next morning and found that we had drifted about 150 miles towards Africa, kind of towards 6O1 land or maybe FL8 land. I was thinking of the money I would save if we did drift all the way to Africa because that was the general direction I were heading when I left the Indian Ocean and this would be a cheap way to get there. I asked the captain if he wanted me to summon a towing ship and he said, "absolutely no". The Captain was the only one on board who thought this cabin door could be mounted so it could be used for a jury rudder as he called it. You try sleeping on a drifting boat in the Indian Ocean monsoon and you find that its tough to even stay in the bunk, much less sleep. I don't think many slept on board the few nights we were tossing all over the place. Remember all the decks were loaded and completely covered with those large turtles when all this was going on, no place for a fellow to walk and all those fellows scampering all over the place, trying to not step on those turtles, and no place to step, and after all the decks got wet those turtles started slipping all over the place. Even a few slid overboard too. Some died and began to smell. Oh yes we were having a time on that boat. These turtles have been known to take a bite out of a leg now and then, so no one hestiated while walking over and between them, needless to say. I was on the air of course most of the time telling the boys about things as they were. We were in daily contact with VQ9HB on Mahe, and a number of times the captain talked directly with the owner of the ship. Even the ships owner asked the captain if he wanted a tow vessel sent out to tow us to either Africa or the Sevchelles. To this the captain always said "no". This captain was as hard as nails and like a bulldog. He was not going to give up as long as there was any hope of getting that cabin door mounted in place of that rudder. He was the only one who thought this was possible. Everyone else had a long time ago given up this as out of the question and impossible to be done. Even I had now given up. After three days the turtles really started to smell Q5-S9+ 50 DB, but still they were back there fighting that rudder. And at long last they got it mounted kind of all of a sudden and I think sort of by accident! We were back in business and a ship with a rudder was again on its way to VO9 land.

A message was sent to the ship's owner on Mahe and back came a message telling us a champagne party was planned for all hands upon our arrival to Port Victoria. Back went a message from me saying, "Make Mine, Cokes, please!" Back came a message to me saying, "It's Cokes for you, Mr. Browning". A letter or news item from Harvey Brain was sent to their local newspaper which was very interesting to read. Oh yes, There was a hero in the article you can bet Guess who? The cabin door proved to be not quite large enough and to keep the ship on course the speed of the engine became the directional control. The usual speed as I remember it was about 250 RPM, but to hold us on course it was reduced to about 175RPM. But we were headed towards VQ9, so everyone was happy. I would say a few drinks were consumed on board that night by everyone except me since there was no Cokes on board by now. They had long ago been drunk. It took us about 10 days to reach Port Victoria, with quite a lot more dead turtles on board. We were a smelly crowd when we arrived there. The local police band were on hand to welcome us back to VQ9 land. We were the heroes of the hour. Cases of Champaigne were brought aboard and one full case of Cokes for me with plenty of ice. I sort of would sav maybe a few fellows got drunk that evening on the boat while it was docked there at the "long pier" at Port Victoria. At least that was another one I walked away from, and one more portion of a DXpedition salted away. Back I went to my little thatched hut that's called a hotel room on the north east side of VQ9. The old antennas were put up and on the air as VO9A again I went. The very first QSO I had was with that fellow in EP2 land-he was some high official in the U. S. Embassy or Consulate there and he told me a very interesting story. He said there were some U. S. destroyers in Zanzibar on some sort of tour down in that area and he got a message to them to sort of stand by with helicopters on board to be ready at a moments notice to be able to take off the ship in case we

got into any difficulties and in danger of sinking. I for one was glad we did not have to call on him for help. I am sure Peggy and the kids felt that same way, and especially the insurance companies. It did sort of worry me to think that the insurance companies were worrying. I did not want our DXpedition to end up here because it was just getting started, you might say. There were lots of places to go to yet and operate from. After operating from VO9A for about a week while QRX for a ship to take me to Mombasa, Kenya, I sort of hated to leave VQ9 land with all the beautiful scenery around there. But you know the DXpedition must go on, and this one was not about to stop yet. Everything was taken down, carefully packed, everyone told "good bye". etc. No customs troubles at all. (There is usually none when leaving you know). I was off to Mombasa and then into Africa on the next leg of my trip. More on that next month.

Technical Aid Group

The first members of 73's Technical Aid Group are listed below. They are willing to help other hams with their technical problems. If you have a concise question that you think can be answered through the mail, why not write to one of the hams on the list? Please type or write legibly, and include a self-addressed stamped envelope. One question to a letter, please.

If you'd like to join the Technical Aid Group and you feel that you are qualified to help other hams, please write us and we'll furnish complete information. It's obvious that we need many helpers in all parts of the country and in all specialties to do the most good. While 73 will try to help with publicity and in other ways, we want the TAG to be a ham-to-ham group helping anyone who needs help, whether they be 73 readers or not.

TRW Catalog

TRW Semiconductors has just announced their 1967 short form catalog. This 20-page publication lists all TRW transistors, diodes, and other semiconductors. Copies are available from TRW Semiconductors, Publications Dept., 1100 Glendon Avenue, Los Angeles, Calif. 90024.

Jensen Tool Catalog

Hams often have trouble finding the special tools that make electronic construction pleasant. Even the large mail-order catalogs don't carry all of the specialized tools we like. We've recently found out about a very extensive (58-page) catalog of tools that contains just about anything you're likely to want or need from eutectic solder to #80 drills. The catalog includes many standard tools, too. Prices are good, and there's no minimum order. Write for a free copy of catalog 266. Jensen Tools, 3630 E. Indian School Road, Phoenix, Arizona 85018.

Solid-State Communications

Here is another book from the staff of Texas Instruments on the design of transistorized communications equipment. brand new book provides the latest information on the design of equipment using FET's, dual transistors, junction transistors and the latest germanium and silicon microwave transistors. This excellent book covers the entire rf spectrum from high-frequency through UHF; it provides much practical information on the design of circuits and in the selection of semiconductors for these frequencies. Some of the topics covered are small signal UHF circuit design, high input impedance techniques, harmonic oscillators, noise characterization of VHF and UHF amplifiers and VHF measurement techniques. \$12.50 from your bookstore or write to Mc-Graw-Hill Book Company, 330 West 42nd Street, New York, New York 10036.

Drake Converters

R. L. Drake Co. has just announced that they're making FET converters for six and two meters. The converters feature low noise and exceptionally low cross modulation, excellent image rejection and flat bandpass. Each converter uses field effect transistors for the rf amplifier and mixer stages, and regular transistors in the local injection section. For full information of these new converters, write R. L. Drake Co., Miamisburg, Ohio.

Technical Topics

The best, most interesting single book for the average ham might well be Technical Topics for the Radio Amateur, by Pat Hawker G3VA. This book is a collection of short notes, interesting ideas, and hundreds of good schematics about simple and complex, common and unique, useful ham radio circuits. G3VA writes the very popular column Technical Topics in the RSGB Bulletin, and much of the material in the book is from this column. TT is a densely-packed, thoroughly-practical 100-page book every building ham should have. The price is only \$1.50 from 73, or you can order for 10 s. from the RSGB, 28 Little Russell Street, London W.C.I, England.

Transistor Circuit Analysis and Design

The 2nd edition of this famous transistor sourcebook by Franklin C. Kitchen retains all the readability and first, but the many revisions the bring this new volume right up to date. In addition to information on junction transistors, this new book places emphasis on the field effect transistor and its operation, tunnel diodes, controlled rectifiers, unijunction transistors and microelectronics. Fitchen spends considerable time in explaining the fundamental circuit properties of transistors and proper ways of biasing them before proceeding into the design of amplifiers and communications circuits. Many practical examples are used throughout and a knowledge of algebra is all that is required to understand this excellent text. This book is highly recommended to the amateur or technician who wants to know the whys and wherefors of transistor circuit design. \$8.50 from your bookstore or write to the publisher, D. Van Nostrand Co., Inc., 120 Alexander Street, Princeton, New Jersey.

Solid State Sales Catalog

Solid State Sales has a new catalog of inexpensive semiconductors and other parts. It's well illustrated, and contains hundreds of components with good prices. You can get a free copy from Solid State Sales, P.O. Box 74, Somerville, Mass. 02143.

Handbook of Transistor Circuits and Measurements

Most books designed for textbooks and engineering aren't as useful to the ham as they could be. Hams don't want to wade through a lot of derivation of mathematical formulas and such to find a circuit they need, or have to figure out a lot of values on what is obviously a fairly standard type of circuit. That's why the new SEEC book, Handbook of Basic Transistor Circuits and Measurements by R.D. Thornton et al looks so interesting. The book contains practical circuits for about every transistor use you can think of, and even gives parts values and transistors for each. The transistors are specified by general types, such as silicon, high speed, amplifier, which makes it easy to use either the newest, cheapest transistors, readily-available transistors, or surplus transistors, depending on your tastes. The book also includes enough technical material and data on measuring transistor characteristics to make the book very useful to the engineer who wants a good reference. The book costs \$4.50 clothbound, or \$2.65 paperbound, Publisher is John Wiley and Sons, 605 Third Avenue, N.Y. 10016.

Shure Reactance Rule

Figuring out resonant frequencies, reactances, Q's, etc., with the standard formulas and arithmetic isn't much fun. A much easier way to do it is with the Shure Reactance Slide Rule. It's easy to learn, easy to use and easy to buy at only \$1 from the Sales Department, Shure Brothers, 222 Hartrey Avenue, Evanston, Ill. 60204.

CONVERTER SALE

6 METER SOLID STATE RF CONVERTERS

2 db NF, .2 μv for 6 db signal to noise ratio, mil. spec. epoxy glass printed circuit board, variable forward gain control, built-in power supply available for all models. 2N3823 FET front end available for 1.5 db NF and reduced cross-modulation effects.

THESE CONVERTERS CAN REALLY PULL IN THE DX!

Model	Input M Hz	Output M Hz	Price

(W2NSD from page 2)

public servants resting behind their barricaded desks. We made it through in about an hour, possibly an all time record. You have to pay to get out of Lebanon and pay to get into Syria. You pay for yourself and you pay for the car. You pay and pay and pay.

After an hour or so of driving through desert and mountains we began to come to civilization . . . an occasional house built on the side of the hills. An interesting thing: the water supply for these houses came to them via a ditch dug into the side of the hills. All of the houses were below the supply ditch, which went on for miles and miles, winding along so that gravity carried the water. Below the houses was a second ditch for waste.

We arrived in Damascus just before dark and, after driving around for a few minutes to get our bearings, we started looking for a hotel . . . a hotel that had air conditioners sticking out of the windows of its rooms. It was about 90° or so and we'd learned the hard way in Cairo to settle for nothing less than good air conditioning. I never thought I would go into a Hilton hotel, but a couple of nights in the Shepheards in Cairo and I no longer cared if Conrad got a big bite out of me.

Just as we were disparing of finding air conditioners we came across the Hotel Cattans. Luckily they had one cool room left so we checked in. I called Rasheed and announced that we had arrived. His son arrived to pick us up a short while later and we drove up and up the side of the incredibly steep hill overlooking the city. About half way up, just before the slant became a vertical cilff, we pulled up in front of a nice home.

Rasheed and his wife welcomed us. It was still quite warm so we went out on his patio

Rasheed YKIAA

and had some cool drinks, talking ham radio and looking down on the twinkling lights of the oldest continuously inhabited city in the world. Off in the distance we could see the camp fires of the refugees from Israel, thousands of them.

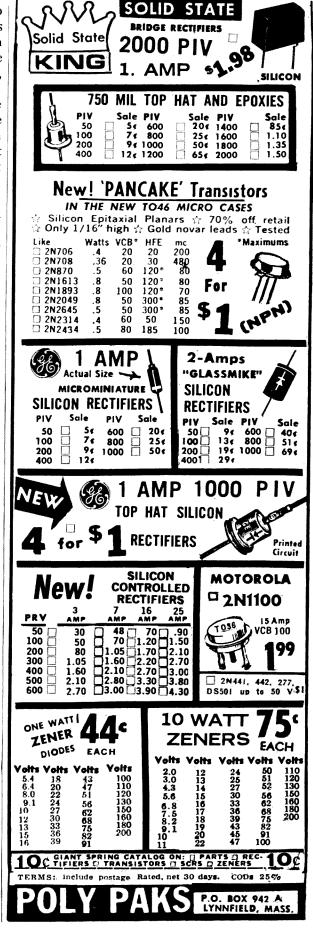

I was most anxious to put YK1AA on the air and see if I could beat down some of the pileups. Rasheed does the best he can with this, but it is very difficult for him, not having been raised in English, to pull out call letters when they are all in a jumble. Rasheed pointed to his three element beam out on the edge of the patio and I could see why he makes most of his stateside contacts via longpath. The U. S. is directly into the mountain for him and very little rf can get through the shield.

I tuned the band anxiously . . . a couple Europeans, nothing more. Damn. My schedule time with my home station in New Hampshire came around so I gave Jim (WA6BSO/1) a call. I1DFL came back and offered to relay for me. Jim was in there, about an S-1, and my signals were about the same. Through I1DFL I found that everything was going well at home. After a few more short QSO's with friends in Asmara, Stockholm, etc., I gave up and returned to Rasheed and the talking. I1DFL had explained that Jim was the only U. S. station that he could hear on the band, so conditions were particularly bad.

Rasheed works at the airport keeping the electronic gear running. He is high enough in the government so he is able to stay on the air during political shakeups, but not high enough so he gets shot. I don't think he is looking for too much in the way of promotions . . . hi. None of the other hams in Syria are permitted to operate.

The next morning Rasheed met Jim and me at the hotel and we walked to the historical museum. The sophistication of some of the things they made all the way back to 6000 BC is amazing. We would be hard put to duplicate some of the glassware they turned out.

Next we headed for the bazaar section of town. I found an ice cream store right off the bat and yanked them in after me. Fellows, it is like nothing you've ever tasted before. They grind out the usual Dairy Queen slush, put it into freezing vats and then pound it with giant potato-mashers so that the crystalline structure breaks down and the ice cream gets very sticky. They serve it by scraping it out of these vats and putting it into dishes with their fingers . . .

The DXERS MAGAZINE c/o W4 BPD

Route I, Box 161-A, Cordova, S.C., U.S.A. then a little sprinkle of pistachio nuts. Jim blanched at the finger bit, but we put a dish of ice cream in his hand and he had to gulp and eat it. I'll try anything.

We went across the little alley into a souvenire shop. I bought an inlaid backgammon board and a hand embroidered damask table cloth and napkins. I'm not sure why because I haven't played backgammon in twenty years and I don't even have a dining room table. Well, you never know when someone is going to knock on the door and invite himself in to play backgammon . . . I'm ready now.

Rasheed took us into out of the way corners of Damascus where we were able to see craftsmen making all of the usual and unusual peculiar to the city. Things like men sitting in their little stalls turning a wood lathe by hand and holding the cutting chisel with one foot, making parts for chairs.

Lunch was spectacular. Rasheed's son manages the finest restaurant in town and he put on a complete Syrian dinner for us, soup to nuts. The soup was yogurt-like, with egg shaped meat balls made out of meat and wheat, but hollow . . . try making something like that sometime. Delicious. The food kept coming and coming and coming . . . we ate for about two hours . . . smoked egg plant (I hate egg plant, but this was great) . . . mashed chick peas with lemon and sesame oil . . . we waddled out into our rented Simca and, with a short prayer that the odometer would continue to be stuck (it froze on the way over . . . heh, heh), we headed back to Beirut and a cocktail party in our honor by the OD5 gang.

Damascus is a fascinating place . . . most of it is very very old, but newer houses are springing up in the suburbs. Few tourists get there, relatively, and as a result the people are very friendly and smiling. None of this running up with the hand outstretched that we had to continually battle against in Kenya and Egypt. After a while you just hide your camera and stop taking pictures in those places.

The border crossing on the way back was faster . . . only about a half hour plus \$3 each for visas. The damned odometer started working again in spite of our extreme care in not jiggling it. Oh well, it would have been hard to explain the border crossing stamps on the car papers with only half enough miles on the odometer.

Beirut is a rather modern city and certainly the most international in the near east. Their currency is free so you don't have

Bob ODSBZ

to shop around for money bargains on the black market. The only major problem we had with the city was in finding our way around while driving. We had a map alright, but none of the streets have names on them so once you lose your place on the map you are lost . . . and the map doesn't have all the little streets on it so you get lost right away, no matter where you head. It took us over an hour of bumbling around to find our way out going to Damascus and almost as long finding our way back in on our return.

The cocktail party went off just fine and we got to meet about ten of the OD5 gang in person. Lebanon is in excellent shape as far as ham radio is concerned. Licenses are simple to get and there are a goodly number of Lebanese licensed. The other near eastern countries would do well to use Lebanon as an example in business and amateur radio.

After the party at Bob's apartment (OD5BZ), Bob and I drove to his shack, down by the water. It is no wonder that Bob has one of the outstanding signals from this part of the world . . . what a location! I worked about a hundred fellows before calling it a night.

The next stop on my trip is Baghdad Wayne

COMPRESSION AMPLIFIER \$29.95

These government surplus limiting amplifiers offered at a fraction of their cost and they are brand new unused. Input & output impedance of 600 ohms. self contained 115 volt 60 cycle power supply. Gain 36 db plus or minus 1 db. Upgrade your shack for professional performance with this beautiful rack panel commercial grade equipment. DB out meter on front panel.

RT-122/APW-11 REC.-TRANS.

RT-122/APW-11 REC.-IKAND.

RT-122/APW-11 Reciver-Trans.—Unit consists of a tunable receiver cavity, a crystal detector, a video amplifier, decoding circuits; a transmitter and circuits for obtaining audio frequency tones from the pulse position modulated signals of the AN/MSQ-1. The transmitter contains circuits for encoding the reply by varying the spacing between the two reply pulses. The Rec.-Trans. receives input pulses transmitted at a pulse repetition frequency of 410 cycles per second and a preset carrier frequency ranging between 2680 and 2920 MC. The reply pulses are automatically transmitted at a preset carrier frequency ranging between 2700 and 2950 MC. Tubes: 11/12AT7: 2/2D21; 6AS6; 6AL5; 2C40. Size: 13 x 5½ x 6". Wt.: 19 lbs.

PRICES: Used, with Tubes—\$14.95. Used, less Tubes—\$5.95.

never say die

I see that ARRL is still leaving no stone unturned to try and kill off the Institute of Amateur Radio. They've done their usual thorough job of making sure that the League is the only national amateur organization. Not that the Institute is dead, by any means, it's just a definite unsuccess.

The responsibility for the failure of the Institute to succeed is largely mine. I know when I started it that it would be fought by every means possible by the ARRL and I was sure that CQ would be as truthful as usual in reporting about it. But I am an incurable idealist and somehow convinced myself that enough amateurs would be interested in helping to keep amateur radio going to overcome the barrage of lies and distortions.

Let me go back and explain. As one of the three officially recognized amateur radio delegates to the 1959 ITU conference I had an opportunity to see at first hand the workings of that organization. I was incredulous that amateur radio went into that conference almost totally unprepared. I felt that we had been deceived and completely failed by the ARRL. I watched the two League representatives living it up in millionaire style . . . they managed to spend over \$15,000 of the ARRL funds in just a few weeks. The complete failure of the League to get support for amateur radio, even within the U.S. delegation, was incredible. I talked with the other members of our delegation to find out what had gone wrong and what could be done to see that this didn't happen again.

I'm afraid that they all thought I was very naive . . . and I guess I was. I had not recognized just how important Washington was until then. This is where everything comes to a head . . . this is where it happens. Each of these gentlemen explained patiently to me that amateur radio was at the very bottom of their list as far as priority in frequency allocations was concerned and that it would remain that way as long as

we did not pressure where it counts: on Congress.

They pointed out that every other major user of radio frequencies maintains a lobby in Washington to look after their interests. They wondered if I thought that all this money would be spent on lobbies if they weren't well worth the investment? Then they brought up the fact that every other major hobby group looks after the interests of their field by having a voice in Washington. I certainly can't argue the effectiveness of the American Rifle Association, the Aircraft Owners and Pilots Association, and many others.

Amateur radio, they laughed, has no voice in Washington. But what about the League counsel in Washington? No, son, this gentleman can only represent the ARRL in dealings before the FCC and cannot, by law, approach any Senators or Congressmen in behalf of the League. No, if the League were to lobby for amateur radio in any way they would have to give up their tax-free setup and operate as a regular business. The law just does not permit tax-free organizations to try to influence legislation.

If a voice in Washington is of such great importance, why is it, I asked, that the ARRL doesn't give up its tax-free situation and do the job that will protect our future? They are the obvious ones to be lobbying for amateur radio. The answer was dollars, of course. Loss of the tax-free government subsidy of the League might cost them well over \$100,000 a year, forcing them to either increase the subscription rates to QST or else cut down on the number of high salaries being paid. Neither course is desirable so we have no lobbying permitted by the League.

By 1963, 73 had reached a size where I thought we might be able to get something started to fill in this lobby gap in amateur radio. Time seemed to be growing short too, for in 1959 the USSR came to our rescue and put off the changes in our frequencies until the next ITU conference and this seemed to be headed for us in the late 1960's, leaving not much time for building up support both within the U.S. and internationally. The Institute of Amateur Radio was formed with the major job of lobbying for our hobby in Washington.

It was never the purpose of the Institute to compete with the ARRL as an alternate organization for amateurs to join. The In-

Special features

Have you looked through this 73 yet? If not, thumb through quickly. We've got a special feature for you in this issue. It's the book(let)-length article, "73 Useful transistor Circuits." Jim Fisk W1DTY has spent a lot of time and work on this feature; from the looks of the results, the time was well spent, for he's done an excellent job. It will be a rare ham who doesn't consult this section often in his building. If you like it, be sure to drop Jim a line. I suspect that he's got at least 73 more circuits that he could use to make "73 Transistor Circuits part II." In fact, he'd probably like to have your suggestions and contributions for part II.

Our book-length features have been very popular, and we look forward to publishing many more. If you have any suggestions for topics, be sure to let us know. And don't forget that we're in the market for booklength manuscripts. If you have the time and ability, and would like to work on one, please write me with an outline of what you'd like to write about. Preparing a manuscript of this type is a lot of hard work, but very rewarding in both personal satisfaction and in the payment.

Special issues

Next month's issue is our April special. This April, we've got a double bonus for you. First, we'll have a sideband section. It will contain a listing of all commercially available HF SSB transceivers, transmitter-receivers and linear amplifiers. If you're thinking about buying some sideband gear, reading this section is a must! You'll want to study the specifications, descriptions, photographs and comparisons of all the gear. In fact, you'll have a strong will if you don't rush to your dealer or mail in an order for some new equipment after reading it.

The second special feature in April is too horrible for words and too secret to divulge. We can't let the rat out of the bag yet, but we will warn you: Be Prepared. It's even worse than last April's Playboy spoof. I suspect that 777 people will cancel their subscriptions after seeing it.

Our May issue will be devoted to quads. Amateur interest is very high in these excellent antennas, and we've get many good articles about them. They range from a full-size quad for forty to a quad-quad-quad for VIIF. We've also got articles on construction of quads, simple quads, and quad masts. This issue will arrive in the midst of the spring antenna season and should result in many antenna parties around the world as hams decide to improve their signals on both transmit and receive.

June is our surplus month. This year, we're planning to have plenty of good surplus articles and, hopefully, many pages of surplus ads. If you'd like to write a surplus conversion for us, remember: 1. We only want conversions on available gear. 2. We don't want rehashes of old articles. 3. Do it now.

A note to surplus dealers: Start preparing now for our surplus issue. It's the finest opportunity to sell your stock you'll find. If you've got a lot of presently useless stuff, put some clever hams to work on uses for it; maybe it's even worth an article in 73.

This year's ARRL National Convention will be held in July in Montreal in honor of Canada's Centennial and Expo 67. We're going to do what we can to honor the amateurs of Canada by featuring articles for and by Canadian hams in our July issue. Many of the articles will be technical; others will look at the Canadian amateur scene—the ridiculously high prices Canadians have

Rod C. Rigg W6YGZ 1305 Occidental Ave. Stockton, Calif. 95203

A Transistorized Digital Identification Generator

Here is a description of an exotic, yet very desirable, unit that will send your call or other information automatically without any motors or other moving parts. It can be built for about \$15.

This is a description of a fully automatic, solid state, no moving parts, digital device for storing and generating upon command, a call sign or other message, in the form of dc to operate a keying relay for telegraphy (cw) or a tone to modulate the carrier for mcw. It contains all standard, commonly used, digital circuits; the flip-flop, multivibrator, and diode "and" and "or" circuits. A rough estimate of cost of parts, if you buy components at surplus and quantity prices as we do, totals \$15.

Just what does it do? Briefly, you push the button and it sends your call or any other message that you want to "program" into it. When it has sent the message once, it automatically stops and waits for another command. It is not possible to inadvertantly "erase" the message for it is "built-in" with the wiring of the diode memory. Changing the message is a simple task requiring only:

1) the design of the new diode matrix, and
2) wiring the diodes into their new places. A typical call, such as W6YGZ, takes 47 diodes in the memory.

"Necessity is the mother of invention" and such is the case with the identification generator as we will henceforth call it. We needed a cheap and reliable unit for identifying our transmitters for tests under long periods of unattended operation (within legal limits of course). We had considered

Fig. 1. Graphical representation of the word "at."

the other methods. A tape recorder uses moving parts and the tape wears out rapidly. A code wheel or perforated tape unit also uses moving parts. All require frequent attention to alignment, adjustment, or replacement of worn parts including tape. What we needed had to be reliable for long periods of time, cheap, compact, and capable of changing the call with nominal effort.

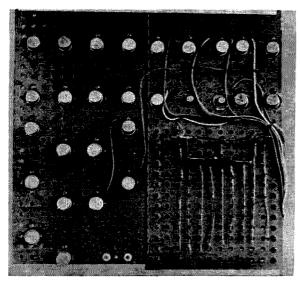

The digital computer approach was favored because of the authors' background and familiarity. The unit was designed using "digital sequential circuit design techniques", a specialized branch of digital computer design, which is a carry-over from relay circuits.

It is assumed that the reader is familiar with the basic digital circuits; AND, OR, FLIP-FLOP, MULTIVIBRATOR, INVERT-ER. Several references cited in the bibliography treat the subject well. The QST, August 1965 article gives a quick review.

A diode matrix was chosen for the memory unit because of the author's immediate familiarity with this type of memory. Different types of memory are presently being contemplated including a fixed magnetic core and a programmable magnetic core type.

A characteristic of this unit which is common to all three types of memory mentioned is that the stored message is changeable; requiring the replacing of diodes in the diode matrix, rerouting sense lines in a fixed magnetic core memory, or simply re-storing a new message in the programmable magnetic core type.

One of the basic questions which arises in the initial design is: in what way should the message be broken down and stored?

Top view of the digital identification generator.

Important criteria in this decision are memory size, circuit complexity, and the ability to store many types of messages. There are three ways in which a message or word can be broken down:

1) By letter, This would require a memory capable of remembering any one of 26

letters, 10 numbers, and certain other characters. It would not require many memory locations. A short message such as a call would only contain 5 or 6 letters and numbers.

2) By character, i.e. dot, dash, or blank. This would require a memory capable of storing one of three possible characters. More memory locations would be needed for the same message than for method 1) as each letter would contain from one to six characters (period has 3 dots, 3 dashes). The call W6YGZ contains 23 characters including spaces.

3) By baud. A baud is a telegraphic unit of time, a dot is one baud, a dash is three bauds and a blank is three bauds (the term is more commonly used in teletype). A unit of this type need only remember one of two characters, presence of a baud or no presence. For example, the letter "a" would consist of a single baud followed by a space baud followed by three more bauds for a total of five locations. An advantage to this system is that only one of two characters need be remembered leading to the binary

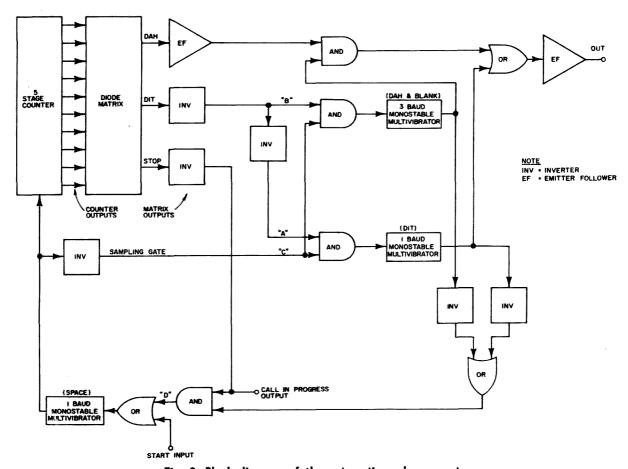

Fig. 2. Block diagram of the automatic code generator.

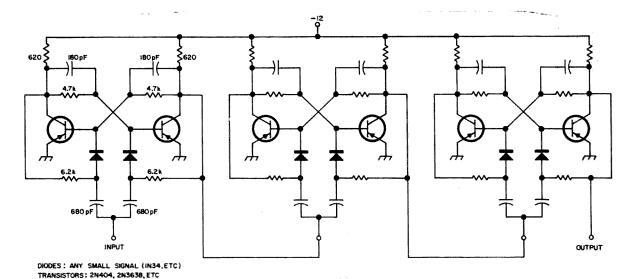

Fig. 3. Typical three stage counter.

system of one, zero, for the memory. The number of locations would be exceedingly large.

Method 2) seemed to be the most practical in light of the criteria involved, so it was chosen for this unit. A memory capable of three characters is only slightly more complex than a two character memory (method 3). The tremendous saving in number of memory locations for a given message is the deciding factor.

Using this method, it is only necessary to build a memory to provide signals which will, at the proper times, trigger circuits generating the dot, dash and blank (no letters). These circuits are simply monostable or one-shot multivibrators with width times of one baud (dot), three bauds (dash), and three bauds (blank).

As an example, consider the message "at". It consists of a dot, a dash, a blank for between letters, and a dash. This is illustrated graphically in Fig. 1. Using the following abbreviations; t = dot, a = dash, b = blank, the memory would be called upon to provide the following signals: t a b a.

So far so good, But there is one more problem; we must provide a short space between characters. If this were not done, the characters would be run together. An additional monostable multivibrator is needed to delay the beginning of the next character until this space time is over. This time is called a "space". It is not to be confused with the blank, which is an absence of a character denoting the spacing between letters. The "space" occurs between characters.

We have established that we need four different time segments corresponding to the four parts of the telegraphic code: dot, dash, blank, and space. Since the length of time for the dash is the same as that for blank, it is a simple matter to combine them into one multivibrator; hence, the dash multivibrator doubles as the blank generator. We need only insure that there is no output during the blank time.

Previously we mentioned memory locations. We prefer to call them states. The capacity of a system is the amount of information it can store and generate and is determined by the number of different states or combinations that system can have. These states are identified by the various values of the counter. Thus, the length of message that can be stored is dependent on the number of counter stages. If the counter contains five stages; then, counting in the binary system, we can determine 32 unique states, i.e. there are 32 possible combinations of counter outputs. Each of these combinations is called a state; and each state can be identified with one character of the message we have stored. 32 bits is enough capacity for most amateur call signs.

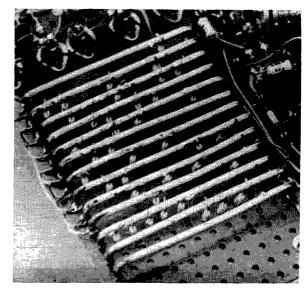

As mentioned previously, this unit was designed using sequential circuit techniques. This means that there is no clock to pace the system; it goes on its own timing. Each circuit triggers the next and so on until it decides to stop. It will be best to keep this concept in mind when reviewing the operation of the system.

Reference to the block diagram, Fig. 2, will show the main components of the sys-

tem. They will be discussed in this order; counter, diode matrix, character formation generators (multivibrators), space formation generator, output circuitry.

The counter, a five stage binary counting chain, determines the particular state of the system and hence the next character to be generated. It consists of five bistable circuits or flip-flops which are connected in cascade so as to count input pulses up to 32 then reset. Outputs are taken from each flip-flop and fed to the diode matrix. A diagram of a typical three stage counter with its interconnections is shown in Fig. 3.

It is in the diode matrix that the message is stored, hence it is the heart of the system. The matrix intreprets each state of the counter and feeds a signal to one of the character formation generators. "Diode matrix" is just a fancy term meaning a col-

Oblique view of the diode matrix that determines what characters will be generated.

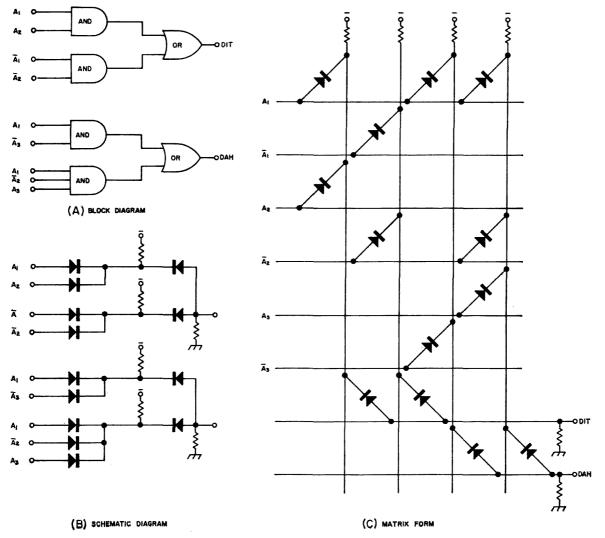

Fig. 4. The diode matrix in three different representations: A. Block diagram. R. Schematic diagram. C. Matrix form.

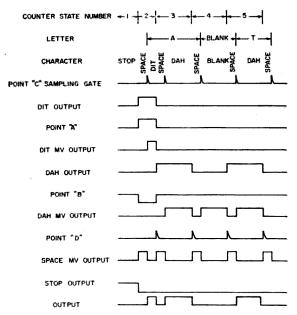

Fig. 5. Timing diagram for generating the word "at."

lection of "and" and "or" circuits that have been arranged in an orderly mammer.

Obtaining the "equations" for setting up the diodes in the matrix is the only complicated portion of the design of this unit. It is necessary to determine the arrangement of diodes such that either output line. dot or dash, has the proper signal or absence of signal for each individual state of the counter. Obviously it is desirous to do this with a minimum number of diodes to keep the cost, complexity, and size down. The actual techniques are a bit beyond the scope of this article. However, they may be found in several of the references in the bibliography. If you are planning on building a similar unit, we will design the matrix for your particular message for a small cost.

The diode matrix is simple in appearance but complicated to design. A typical block diagram is shown in Fig. 4A, its corresponding schematic diagram in Fig. 4B, and the same circuit in matrix form is shown in Fig. 4C.

Simply stated, the diode matrix consists of two level structures of "and" and "or" circuits which select the proper states of the counter and provide outputs during (and only during) those states.

The design procedure involves Karnaugh mapping and writing minimal equations. The matrix can easily be built from the equations.

We have not set a definite charge for the

service. The time required to develop the equations depends on the nature of the message, the amount of "professionalness" of the code desired and the degree to which the design is minimal (i.e. minimal cost). An estimated typical time for a call would be two hours.

We would like to see our device built by someone else and would probably charge only a nominal fee if the person can show a bona fide interest. The design fee is to discourage non-interested persons from wasting our time.

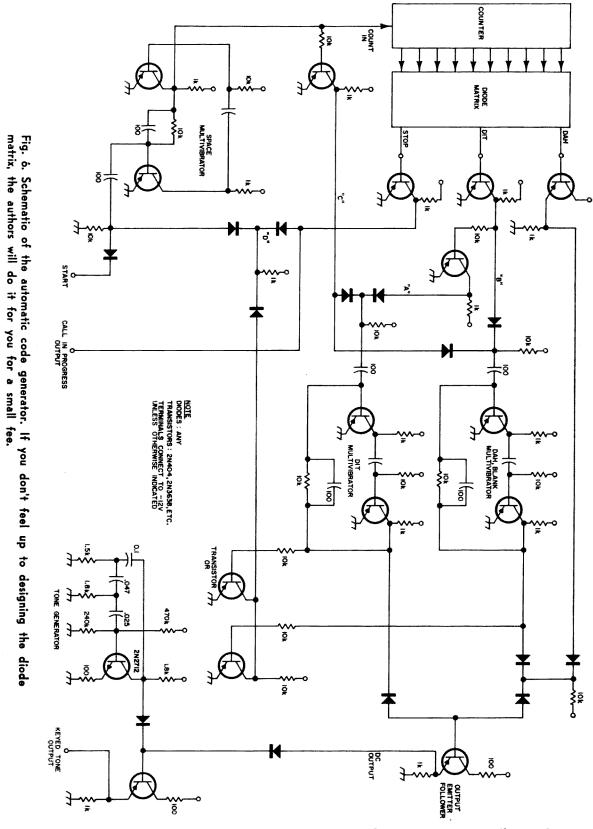

The character formation generators, as stated previously, are monostable multivibrators. These two circuits are triggered by the outputs of the diode matrix. A dot output triggers the one baud length MV (multivibrator), a dash triggers the three baud MV which together with the dash output in an AND circuit causes an output. The blank also triggers the three baud MV but there is no output.

When either of the character multivibrators has completed its function, the space multivibrator is triggered. The space MV, sends a pulse to the counter when it is first triggered. This moves the counter up one state. When the space MV is completed, a pulse is sent to the sampling gates which in turn gates a pulse to either formation MV depending on the output of the diode matrix. And the cycle repeats itself.

The output circuitry simply combines the outputs of the two character formation generators and gates on and off a tone generator for mew or operates a relay for ew. There is provision for inhibiting an output during a blank.

One last thing which we need to mention is a method of stopping the generator after it has sent the message once. The method is simple. A third output from the diode matrix, called a stop, is provided. The stop output occurs after the counter has completed 32 counts. When the counter reaches that state the stop output gates off the space MV input pulses from the formation MVs. This interrupts the sequence and the unit remains dormant until restarted. To start again, a pulse is fed to the space MV. The next state does not have a stop signal so the space MV input pulses are again gated on and the circuit continues thru its sequence.

The entire unit timing diagram is shown in Fig. 5. A careful study will lead to a

better understanding of the operation of the generator. The example shown has been selected to show most of the details of operation. The following events happen in sequence: The counter is initially in the stop state (no. 1). A start pulse fed to the space MV input turns it on incrementing the counter to the next state (no. 2). The diode

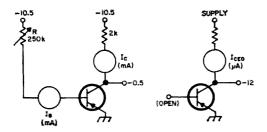

Fig. 7. Circuits for measuring transistor parameters. See the text for a description of how to use these circuits.

matrix interprets this state as a dot. When the space MV returns to its quiescent state, the matrix output is sampled and the dot MV is triggered generating an output. When the dot MV is up, the space MV is again triggered incrementing the counter to the next state. The cycle continues until the stop state again occurs.

Going from block diagrams to actual circuitry; logical levels of "one" are -12 volts and those of "zero" are zero volts. The schematic of our working model is shown in Fig. 6. An understanding of the operation of each of the individual circuits can be gained by reading one of the many texts and articles on the subject of digital circuits. Some of them are included in the bibliography.

It must be kept in mind that we are not dealing with ideal components when building digital circuits; diodes have finite forward voltage drop, finite back resistance, transistors do not have infinite gain nor zero "on" voltage drop. The voltages at each of the logic points are not exactly zero and -12. They are close enough that the circuits still work with good reliability. Keeping the voltages and circuit operation as near ideal as possible is the main criteria in selecting the resistance values for each circuit. Capacitor values determine the timing details. An oscilloscope is handy for debugging the circuits for their final design but is not absolutely necessary.

Typical voltages are not shown on the schematic because each point has a voltage which is continually changing from one value to another. Voltage waveforms at the more important points are shown in the timing diagram.

Obtaining parts at a minimum cost has always been a concern for the amateur. The circuit design of this unit was done with low cost in mind. The surplus market is a good source of resistors, capacitors, and diodes at prices well below the industrial prices you pay for new material.

It is also true that transistors are available at quite low prices but, it has been our experience that the industrial units are more economical and desirable. Most surplus or used transistors are not adequate for digital service and out of a bargain bag of surplus transistors many will not work reliably.

With the introduction of the cheap silicon transistors, it is more economical to consider the industrial units. For example, the transistor used in the identification generator, Fairchild 2N3638, is 31c in quantity. This fact together with the assurance of known characteristics and uniformity of quality makes the choice an easy one. Paul Franson discusses the 2N3638 in his column; 73 Magazine, June 1965, page 88.

Surplus transistors can be used but should be tested first. A few simple tests will determine if a transistor is suitable for use in digital circuits: 1) The dc beta should be greater than 30. DC beta, here, is determined by measuring what base current is needed to produce 5 mA of collector current with the collector-emitter voltage 0.5 volts. DC beta is the ratio of collector current (5 mA) to base current. 2) The leakage current should not exceed 200 microamps. Leakage current, I. is the collector current with the collector-emitter voltage 12 volts and the base open. Circuits for measuring both these parameters are shown in Fig. 7. These are relatively simple tests but they tell quite a bit in comparing transistors. Units that meet these two tests will generally work satisfactory in digital circuits.

Other types of transistors will work equally well. 2N414, 2N404, 2N1305, are just a few. Practically any transistor will work if it meets the above tests. NPN units can also be used if battery and diode polarities are reversed.

Many variations on this idea are possible. Amateurs in the RTTY field might like to consider this unit for solving the problem of dual identification. As the FCC rules stand, only the identification of the transmitting station is required to be in cw. The requirement can be fully met with this generator and a ten minute timer to trigger it.

The ragchewer will find a unit such as this an extension of his "ten minute reminder" (it is suggested that the reader consult the rules and regulations part 97.87 before making final plans).

For the amateur who likes it deluxe, this unit can be the basis for a semi-automated cw station.

With a magnetic core memory many variations of the basic design are possible; for example, several messages can be stored in the memory and called for individually to satisfy various situations. For instance, the following messages could be contained in memory: CQ CQ CQ DE W6YGZ, town, handle, TESTING, 73, and so on. Each could be selected to fit the need. The possibilities are limitless.

For the contest minded (or the novice) a unit with the message: "CQ SS CQ SS CQ SS DE W6YGZ" might be the answer. The message need be stored only once but could be called out three times in a row if a simple three counter is used.

Sideband Proof of Performance

Have you ever checked your gear to see what it can do? It's interesting, and can often lead to improved results.

Broadcast stations are very familiar with the term "Proof-of-Performance". It designates the series of specified measurements that must be made, set down on paper, and filed with the FCC before a station license will be issued. Though no such requirement is made for amateur stations, compiling a similar set of data will probably reveal many things about your installation which are worthy of correction.

The idea of a graphical analysis of the performance of my equipment setup came about when I purchased a new exciter capable of overdriving my linear. It seemed desirable to construct a pad of approximately three decibels attenuation to correct

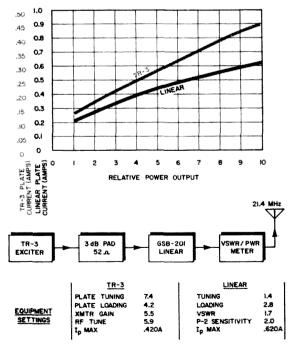

Fig. 1. Plate current of the TR-3 and linear versus relative power output.

the situation. However, to determine the precise benefits, or obtain a quantitative conception of these benefits required some sort of testing. Graphical plotting of the results was the logical approach.

A graph in two-dimensional form shows the variation of a dependent, plotted vertically, when an independent variable, plotted horizontally, is caused to change through a predetermined series of values. The plotting is done after a series of tests have been made at a relatively large number of values of the independent variable and the values of both variables tabulated.

Carrying out a good test requires: 1. a decision as to what items are to be measured, 2. finding an independent (controllable) variable which will put the dependent variable to the test as much as possible, 3. tabulating the results as accurately as possible while the test is being made, 4. putting the results in a form which will best show the variation taking place, and 5. analysis of the results.

Amateur measurements usually fall into the "comparative" class, as access to precise standards is usually impossible and the results are relative to a given set of conditions. Therefore, it is desirable to plot more than one measureable dependent variable if possible in order that accuracy will not depend on any one measuring instrument. Also, the results of one plotted curve can support the results of another, making the analysis more positive.

The results of the first attempt at measurement are shown in Fig. 1 and represent

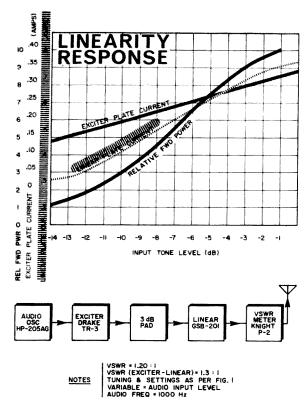

Fig. 2. Linearity response.

a test which could be made quickly and easily by virtually any station with only a VSWR meter with a relative power scale. Carrier is inserted and the level increased as readings of relative power output are taken, along with exciter plate current and linear plate current. This test is informative, but the fact is that the independent variable is not measureable and the results do not show the most important variation, that of power output with input audio level. However it is a reasonably good indication of the linearity of the two stages with drive. An important conclusion from this graph was the fact that the driver (TR-3) reached 450 mA, its maximum output where flattopping begins, at the same time that the linear had only reached slightly over 600 mA. The linear was capable of being driven to slightly over 700 mA before flat-topping; therefore it was obvious that on this band (15 meters) the 3 dB pad presented more loss than desirable. The ultimate conditions was that both exciter and linear flat-top at the same point.

A more valuable test was effected when an audio oscillator was used with the output attenuated to mike level and fed into the microphone input, as shown in Fig. 2. While a commercial unit was used here with

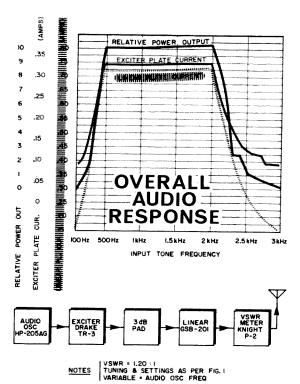

Fig. 3. Overall audio response.

a step attenuator and db level variation read accurately, it is equally as valid to use any audio oscillator in conjunction with a resistor-potentiometer voltage divider to reduce the level and take readings of audio level with a VTVM at the audio oscillator. In many cases, a decibel plot will improve the appearance of a curve over a voltage plot and converting to decibels is not always necessary or even desirable. Use the method of plotting which will emphasize the deficiencies, they are what we are looking for.

In any case, the second set of curves shows that the exciter has become delightfully linear, however on this band (40 meters) it reaches 300 mA plate current when the linear begins to level off. In this case, it would be better to have slightly more padding in order to make the exciter ALC work, thereby raising the average level of rf a few decibels. Another revelation from the curve is the non-linearity in the low plate current region in the linear, a condition which is supported by the relative forward power curve in this region. While non-linearity at this power level is not as serious as at maximum output, it is worthy of some attention in the future.

While the audio oscillator was available it seemed worthwhile to make an overall frequency response run, the result of which

is shown in Fig. 3. In making this run the input audio at 100 Hz was increased until the linear plate current had ceased rising. It would have been preferable, for observation of the "top" of the response curve, if a slightly lower level had been used since it appears that the leveling-off of the amplifier output has produced an apparent flatness across the response that is "too good to be true". However, the exciter exhibits this same condition and perhaps the actual response over this range is not considerably different from that indicated. The more important aspect of the curve is the steepness of the sides. It shows very definitely the fact that the exciter used the steepest side of the filter response on the side toward the carrier. This results in the response encompassing a greater area of lows. Since the apparent "volume" of the voice is carried by the low frequencies, this may account for the seemingly greater "punch" provided by one transmitter over another of equal power.

The small step is the response of the exciter at 2.7 kHz is interesting but probably rather inconsequential.

I have made no attempt here to "doctor up" any of the results nor to minimize the shortcomings of the test procedures. These are the purpose of testing and it is readily seen how the test procedures can be improved and why. It is also appropriate to remark here that when testing anything it is desirable to write down everything possible pertaining to the conditions of the test, whether it seems pertinent at the time or not. The author keeps index cards in the optimum dial settings and current readings on each band. Also, it is naturally best that tests be made under the same conditions that the equipment is used, and this means into the antenna. This dictates the making of overall tests at a time when the band is dead.

A Non-Tiring CW Monitor.

For anyone who enjoys long periods of CW operation, a good keying monitor is a necessity. Unfortunately, most simple monitors which produce a single tone get awfully hard on the ears after a while and many experienced CW operators still resort to using their receivers as a monitor. They do this because of the pleasing tonal quality of the multi-frequency signal and because one can "play" with the receiver tuning to vary the tone.

It would, of course, be better to have a keying monitor that sounds like the receiver signal and to leave the receiver tuning alone. One can come pretty close to this ideal by use of a dual-tone monitor. Some years ago, I built such a monitor but forgot about it when my interest turned to SSB. Now, with a returning interest to CW, I decided to update the monitor using transistors.

The circuit for the monitor is shown in Fig. 1. The circuit is simply two variable

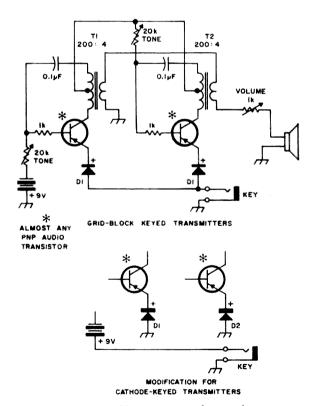

Fig. 1. Two-tone CW monitor designed to overcome the monotony of a single sine wave output monitor. No parts are critical; ell are discussed in the text.

tone oscillators with their outputs connected in series to the monitor loudspeaker. The diodes D1 and D2 protect the monitor from the voltage across the transmitter key terminals. These diodes and the battery connection must be slightly changed as shown for use with a cathode-keyed transmitter.

I used a Telefunken transistor but practically any low-level audio transistor with a B of 50 or more will work. Some examples: 2N138, 181, 186, 217, 223, 249, 270, etc. The diodes D1 and D2 may be any type normal power supply silicon diode units work fine-having a PIV greater than the voltage measured across the open key terminals. A battery supply is shown, however, any operating voltage between 6 and 15 volts is satisfactory and this voltage can usually be "borrowed" from some well filtered point in a transmitter or receiver. If a battery supply is used, the resistance across the open transmitter key terminals should be checked. With some transmitters this resistance is only several thousand ohms and an on-off switch must be used in the monitor to prevent a continuous battery drain.

I built the monitor in a small Minibox measuring 3½ x 2½ x 2½ inches so it could be used as a separate unit for portable operation or as a CPO. It could just as easily be constructed on bakelite circuit board and mounted inside a transmitter. The exact frequency range of the oscillators will depend on the manufacture of the components used but should be about 700 to 2000 Hz. The combinations of tones from two oscillators with this range should satisfy anyone's desire to change the monitor tonal quality.

Although conceived only as a keying monitor, some other uses for such an oscillator suggest themselves: a two-tone test oscillator for SSB measurements and as a CW generator/kewer for an SSB transceiver without CW provisions by feeding the output of only one tone oscillator to the microphone input of the transceiver. For these applications, however, it is essential that the output of each oscillator be checked on an oscilloscope to be sure that it is a good sine wave at the tone control setting(s) used.

Seven Elements on Twenty

Here's a high gain, low cost beam that will really help you get out on twenty meters. Why not join the big boys?

In antenna design, as in boxing, it is true to say "A good big 'un can beat a good little 'un". Tuning across the favorite DX band, 14MHz, proves this axiom again and again as we hear the choice DX returning to the fellows with the big beams mounted on high towers. However, the bigger they are the more they cost, and even though kind neighbors may not object, the financial strain does not allow the average ham the luxury

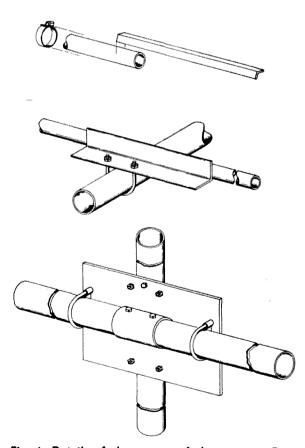

Fig. 1. Details of three parts of the antenna. From the top: Addition of extensions to the ends of the reflector for tuning. Element attachment to the boom. Attachment of the boom to the mast.

of a big antenna. The following description of my antenna is to give some idea of a low cost approach to a large Yagi design on 14 MHz.

The first consideration is the wind load on a large structure—how strong must the beam be to withstand winds to 60 mph? Two approaches were considered. First, a rigid boom using a triangular aluminum tower. Second, a tubular boom with a degree of flexibility to "ride" wind gusts. It was decided to follow the second approach using relatively small diameter tubing, with braces to take the vertical load of the elements.

Sixty feet of boom was selected as a good compromise between cost and performance. For the operator who wishes wide band operation between CW and phone this boom length will allow ¼ wave spacing with five elements. For the phone or the CW enthusiast more elements can be added to give a narrower beam width for better QRM rejection on receive, and a little more gain on transmit. As my antenna was to be used mainly on phone SSB, a center frequency of 14.270 MHz was chosen with seven elements at .15 wave-length, approximately 10 feet spacing.

A visit to the local electrical store produced 2 inch I.D. conduit with .125 inch wall. Two 10 feet lengths were purchased, and a piece cut off each, one foot long, to be used as a coupling between boom sections which are 2 inches O.D. Four lengths of alloy tubing were purchased 2 inch O.D., two at 12 feet, two at 9 feet, wall thickness .065 inches.

Now to assemble the boom on the ground. A screw coupling is supplied with the conduit, so the two 9 feet lengths are coupled together, and two 3 inch, ¼ inch D. bolts fitted through the coupling for added me-

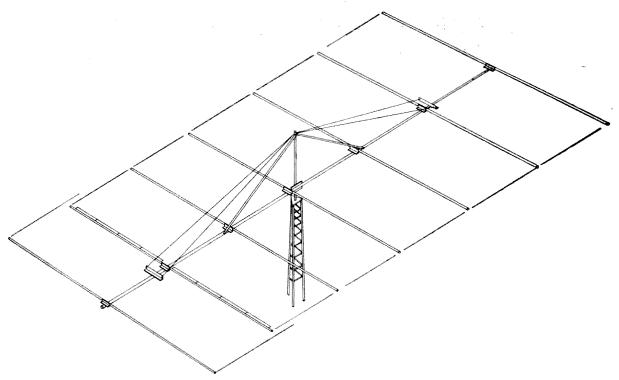

Fig. 2. WA4WWM's seven element twenty-meter beam. Dimensions are given in the text.

chanical security. At either end of the conduit a 3 inch cut is made with a hack saw. Now, a 12 foot length of 2 inch O.D. alloy tubing is inserted in either end of the conduit and a strong joint assured by a 214 inch muffler clamp. These muffler clamps are very strong and cost less than 25 cents each. Six at 2 inch and ten at 2¼ inch were bought from the local auto accessory store. The remaining two 9 feet lengths are joined to both ends of the construction using the two one foot sections of conduit which have been previously slotted with the hack saw for 3 inches either side. This coupling is now made tight with two 24 inch muffler clamps. We now have a 60 foot boom lying on the ground looking extremely flimsy especially when picked up at the center!

Each element is made from alloy tubing. The center portion is the standard 12 foot of 1 inch O.D., .058 inch wall, with another 12 foot of % inch O.D. cut into equal parts, inserted at either end, and still another 12 foot length of % inch O.D. tubing cut in half and inserted into the % inch sections. Now, the beam element is 34 feet long, allowing 6 inches insertion for each joint. Holes were drilled and self-tap screws used to ensure a rigid mechanical coupling. The 34 feet length is sufficient to allow trimming of the driven element and directors, but extra length is required for the reflector, approxi-

mately 9 inches at either end. Two strips of aluminum 1 inch x 12 inches were bent to make ½ inch angle and fixed to either end of the reflector with a hose clamp bought from the auto store. This makes an easily adjustable tuning device.

Various methods of feeding the driven element can be used, but, as K200 UHF twin line was available it was decided to try a folded dipole. Aluminum clothes line wire was spaced 4 inches from the driven element and gave a 200 ohm match to the line. A length of 150 feet of line is used at my location, terminating in a ½ wave coax balun to give 50 ohms to the transmitter. The length of the driven element is obtained from the antenna handbook as 465/F in feet when F is in megahertz. Director #1 was found optimum at 445/F, #2, 3, 4, and 5 progressively shorter to make #5 a 430/F. The reflector should be about 490/F but it is highly recommended that this element be tuned for best front to back ratio.

The elements are now attached to the boom by a 12 inch length of 1½ inch alloy angle fixed to the center of the element with two 1½ inch ¼ inch D. bolts, then the angle drilled to take a 2 inch or 2¼ inch muffler clamp to suit the boom, the three inner elements with 2¼ inch clamps, the four outer with 2 inch clamps.

The element positions should now be

marked, then the whole antenna disassembled. I use a telescoping tower with 20 foot sections, so winding this down gave a relatively convenient height to reassemble the antenna, using a 20 foot ladder to work at the outer elements.

The center part of the boom is now mounted to the mast, which is rotated by a rotor 3 feet down inside the tower. The mast is 10 feet long so 7 feet remains above the tower. The boom is mounted to the mast, again with muffler clamps on a 4 inch steel plate 18 inches by 12 inches. A % inch hole is drilled through the mast and plate and a bolt used here for added strength. Two 12 feet lengths of % inch tubing are now used to support the ends of the inner 18 feet from the top of the mast, again using muffler clamps. Next, the two 12 feet lengths of 2 inch tubing are assembled to the conduit as before. The ends of these are now supported by cable from the top of the mast. A 2 foot cross bar of 11/2 inch alloy angle was mounted with a muffler clamp and the ends drilled to take the two cables from the mast to either end. Two

A shot of the beam with a small quad over it.

turnbuckles at the mast take up the droop in the boom at this stage. The cross bars give some added strength against lateral forces. Now the remaining two boom sections are coupled to the structure. We now have the boom ready to receive the elements. Assemble the outer elements first, keeping the array balanced, and there is—a seven element beam on a 60 foot boom.

Some remarks on tuning are appropriate. The director lengths quoted are close to the optimum but some trimming of the driven clement may be necessary to ensure 200 ohms. It is best to measure this with an antennascope and a 4:1 bolun to read 50 ohms. This is a balanced system, hence the balun. The reflector can be adjusted with the aid of a small oscillator located a few hundred yards away, or by getting a local ham a few miles away to give S-meter readings. The antenna handbooks will supply details.

Finally, a beam of this size helps tremendously in reception, as the half-power bandwidth is 45 degrees. The gain in theory is about 12 db, but signal reports would suggest that this figure is low, especially when optimum conditions suit the vertical angle of radiation. It is highly recommended that a height of at least 70 feet should be used with any beam antenna, especially after the expenditure of time and energy on a large array.

The antenna described has been in use for a year and has withstood winds of 60 mph with no sign of damage. The cost is much lower than the commercial versions available. Some of the ideas in this article may also be of some use in the construction of smaller Yagis at a relatively low cost factor.

. . . WA4WWM

Climbing the Novice Ladder

Part IV: The code is almost conquered.

On a Saturday morning just two weeks after their last visit to FN's shack, Judy and Joe wheeled into the yard and were surprised to find Larry leaning against the basement door jamb. "Hi, Larry", said Joe, "what you doin' out here . . . goin' to sit in on a code class with us?"

"That's exactly what I am goin to do Joe . . . hello Judy; FN phoned me right after you'd contacted me to be Judy's examiner and suggested that I drop out this morning for an informal session with you kids . . . here I am!"

Just then FN appeared, greeted Judy and Joe cordially and explained, "I asked Larry to come out this morning and we'd put you through a little preliminary examination. Nothing official about it of course; just a run-down to get a double check on your progress. So, if you're all set, let's go inside, set up the CPO and see how your code looks. You bring your headphones this time, Joe?"

"Sure thing" Joe replied, "right here" and he opened the carrier pouch on his Honda and pulled them out along with the license manual. Judy produced the ABC's book which she had picked up and the four of them settled themselves in FN's shop.

"Larry, put on the phones and take a

Joe chose to use his SWL receiver—a military surplus BC-312-N—for his novice operation.

listen to Judy's sending; I'll work Joe over when you're through. Let her send simple English with a few figures and punctuation . . . here, you can take a few lines from one of these books" and so saying FN handed Larry the two little manuals.

Picking a short paragraph in Judy's ABC book, Larry donned the headphones and said, "OK Judy; start right here and send me the first three lines in this paragraph."

FN and Joe remained quiet while Larry copied Judy's sending. When she had completed her stint, FN took the phones from Larry and said, "All right Joe, you send these three sentences from the license manual to me while Larry checks Judy's copy".

ual to me while Larry checks Judy's copy". When Joe finished, Larry looked up saying, "Well, Judy did right well . . . just one mistake girl . . . you sent an 'N' where it should have been an 'A'

"I knew it" Judy exclaimed, "the minute I did it but Gramps had told me not to go back and correct a mistake like that in an examination but to just keep going, so I did".

"Right, Judy", Larry returned, "you'd correct it if you were actually communicating with another station but in an exam you'd just foul yourself up. Incidentally, both FN and I are checking the time it takes you to send the copy we give you; we can then figure your transmitting speed by counting the characters. You were doing very close to six words a minute Judy; so close we won't split hairs".

By then FN had counted the characters in Joe's copy, checked his stop-watch and announced, "By golly, you kids are running practically neck and neck! Joe hit it right on the button at six wpm and also made but one error . . . the old 'X' for a 'Y' again Joe; give those letters a lot more play next time you practice. Looks like both of you made sufficient solid copy a couple of times to have put you through the formal exam but as far as I'm concerned, I'd like to see

you both up to 7 or even 8 words a minute both sending and receiving solid copy before we call the turn formally; what you think Larry?"

"By all means, Larry came back, "if you kids can reach 7 or 8, you'll go through 5 like nothing; give yourselves those extra

few words for a bit of leeway".

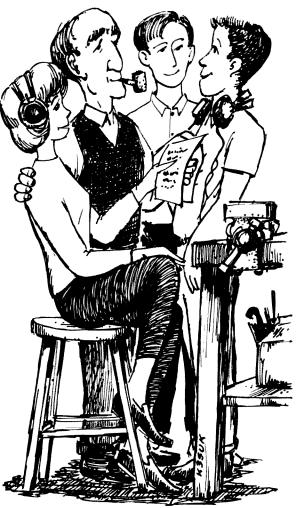

FN then commented, "You should be able to do that in the next couple of weeks if you keep up your present pace . . . just keep plugging. Let's see now what you can do with receiving" and both FN and Larry passed the phones to Judy and Joe.

Larry and FN again alternated between sending and checking copy. Again the two youngsters were very close; Judy had a slight edge and Larry gave her 5.5 wpm whereas FN checked Joe out at exactly 5. Judy generously reminded them that she had a bit more time to practice whereas Joe had his paper route obligation every evening. However, both FN and Larry expressed satisfaction and both were confident that in another two weeks, 7 or 8 words a minute could roll out from under both their fists and pencils. It was therefore mutually agreed that if their knowledge of the written portion of the examination proved equally satisfactory, Larry and FN would administer the formal code examination at the next session, two weeks hence. The written portion would necessarily have to await completion of the formal code test and subsequent receipt of the other papers by FN and Larry. In the meantime, both Joe and Judy, independently, were to write to the Federal Communications Commission at Gettysburg, Pa. and request application forms for amateur radio licenses. They were however, not to complete and return them but were to turn them over to their examiners at the time of the code test.

The code tests for this session having been completed, FN suggested, "Suppose we take up the written portion and see what you know about that in a verbal test; you been

studying your books?"

"Sure, Gramps", replied Judy, "I've been getting in some time every afternoon and I've been reading myself to sleep at night with one or the other of them . . . Joe and I have been swapping them between us. Kinda rough going in spots but Joe's been able to straighten me out on some of the puzzlers so I figure I'm getting the hang of it".

Judy, FN, Larry and Joe talked about receivers after the code practice session.

"Good" was FN's comment, "now how about vou, Joe?"

"Well, FN, I haven't been able to get in as much time as Judy, with my paper route but I think were about even. I've been concentrating on the laws and regulations mostly because a lot of the semi-technical stuff I've had in physics classes and it comes pretty easy".

"OK, then," said FN, "Larry, what say you and I take turns asking them questions at random from the books? You take the license manual and I'll use the ABC's and

we'll alternate the questions".

"Fine" replied Larry, you start if off, FN".

"All right; Judy suppose you tell me what the novice frequency bands are." No trouble here . . . Judy rattled them off like she was using them all every day.

Larry came at her then with, "What is

the maximum legal power allowed novice stations?" to which she promptly replied, "75 watts" but Larry wanted more; "Input or output Judy?"

Looking a bit confused Judy countered with, "Input I think, isn't it? Gosh, I guess I didn't pay enough attention to that."

"Yes, Judy" returned Larry, "input it is but remember you may get a question reading just that way"... what is the maximum legal *input* power.. "and if you were confused between 'input' and 'output' you could go wrong. Have Joe explain this to you more fully some time."

It again being FN's turn, he asked Joe, "What frequency bands can a novice use for radio telephony?"

Joe immediately replied, "145-147 megacycles, only".

After acknowledging this as correct, FN said, let's divert for a moment here; glad this came up. You're right Joe and the use of the word 'megacycle' may appear in your examination or a new term may appear here. Recently a change was mutually agreed upon by industry, educational institutions and scientific organizations. word 'hertz' was substituted for 'cycles per second', therefore megacycle has now become 'megahertz', kilocycle is 'kilohertz' and they've made gigacycle 'gigahertz'. Until the changeover is complete, your examination questions may carry either expression; many of the current manuals and handbooks have not as yet been changed . . . this will take a bit of time. The change was made to honor the memory of Prof. Heinrich Hertz who is the acknowledged discoverer of the phenomena known as 'Hertzian waves' or, as we have more commonly referred to them, 'radio waves'. Just remember that if the word 'hertz' appears where you have studied it as 'cycles', they are one and the same. I'll give you each a card before you leave which shows both the old and the new designations and their abbreviations. Now let's get on with the questions".

After about 45 minutes of this it was pretty evident to both FN and Larry that both youngsters had really done a bit of study ing. Several weak points cropped up of course and they were somewhat hesitant and unsure of the correct answer in replying but in the main, Larry and FN were both satisfied that progress had been excellent. The kids were both cautioned not to

relax their studies and FN would subject them to another informal verbal exam after they completed the code exam at the next bi-weekly session. Just then FN's XYL made her appearance with a heaping plate of freshly baked doughnuts and a pot of coffee, Joe went to the Honda for a six-pack of Coke and FN declared a recess.

While relaxing with this bit of nourishment, Joe broke out with, "Gee, FN; something Larry and I been wondering about for some time and always forget to ask you. We know what the 'FN' stands for . . your 'sine' or handle . . . but how come FN; why not your initials or some other letters?"

FN laughed and said, "Well it's not much of a story Joe. When I first went to work for Western Union as a student telegrapher, I was told that I must choose a two letter combination as my 'signature' to receipt for messages on the telegraph line. My initials, 'DM' would have been all right except that one of the regular operators already used that sine. So I was told to choose any two letter group not then in use and my supervisor suggested something easily recognized and with good rythm. So, I finally came up with 'FN' which in the Morse telegraph code was easy to send and sounded rythmic . . . dit dah dit . . . dah dit . . . that would be 'RN' in the radio code but when I changed over from wire to 'wireless' telegraphy, I was used to the letters FN and it was pretty rythmic in the Continental code as well; just one more dot, like this . . . dit dit dah dit . . dah dit . . . so I just carried it along and I've been FN ever since".

"Should Judy and I have sines too?" Joe inquired.

"You can if you like Joe . . pick your initials or any combination that appeals to you but you'll find most hams and darned few novices will know what you mean when they ask your name and you say 'my sine is YZ' or whatever you have chosen. You'll have to educate 'em to it . . most hams simply use their names. Yours Joe, is hardly longer than a sine would be . . just one more letter and an 'e' at that so you really don't need a sine. On the other hand, Judy's name is kinda long to send though not as bad as many that you'll hear, so if she wants to use a sine, nothing wrong with it. Her initials though are a bit long in code characters . . IM has a dot and five dashes in it . . she may want something shorter and more rhythmic like DA or BR or something."

"How about BK, Gramps?" Judy broke in.

"No" replied FN, "BK is a radio abbreviation meaning 'break' and it would be confusing; don't use anything which may have a double meaning like BT, AR, SK and such."

Judy pondered a few minutes and then came up with, "I'd like to take the Continental code equivalent of your sine Gramps, making it 'RN' . . how about that?"

Looking smugly pleased FN replied, "Sure . . it's OK with me; I don't think any of the boys will take you for a member of the Royal Navy or think you're a Registered Nurse" he finished with a chuckle. From there on out, Judy became 'RN'!

With the little pick-up snack out of the way, FN reminded them that he had promised to talk about the equipment they'd need for a novice station. "Let's start with the receiver; that's the first thing you should have and it wouldn't hurt a bit to get one right now. You could then listen to the many code practice stations sending slowly on the air and to novice and general class hams talking together. Most of them will be too fast for you but in straining to try and keep up you'll find that your

. . . Judy, Larry and Joe parted . . .

code speed will build up a lot faster from the incentive provided by trying to grasp what they are talking about. Always practice by trying to copy a station sending a little faster than you can receive solid; he'll keep you on your toes".

"Now there's several ways in which you can acquire a receiver" FN continued. "First off, you can build one from a magazine or handbook description. I don't recommend this for a beginner and I think Larry will go along with me on this" and Larry nodded in agreement. "First off, today's ham bands are really crowded with stations. That means that you must have a 'selective' receiver . . . one which will permit you to separate them as much as possible. This calls for what we know as a 'superheterodyne' receiver or, as the hams call it more familiarly, a 'super-het'; a good second bet is a really good tuned radio frequency type, again abbreviated ham-wise to 'TRF'. Building either of these is a pretty tricky procedure and after you have it all assembled and wired, it still must be 'aligned' which, to really do right, calls for several special instruments. In the long run you'll have a somewhat mediocre receiver which will cost you about as much as if you had bought a good, standard make, already built and operating. Then too, you can compromise and buy a 'kit' where all of the so-called 'hard work' has been done for you. Holes are punched and drilled in chassis and panel, coils are wound and roughly aligned etc. It's still quite a job to assemble, wire and complete the alignment. An experienced ham can do a good job with such a kit in a relatively short time but the beginner should be wary of tackling it."

"Buying a good, factory-built receiver has several angles also. A really good new one by a reliable manufacturer is going to cost somewhere in the \$150 to \$250 price range. Even better ones go up in price from several hundred dollars to a few jobs selling at a thousand or more! Don't let it scare you though; you are not about to equip 'Gemini Control' but simply making a start in ham radio. You can do rather well with one of the more modest receivers and if it's a fairly recent model of reliable manufacture, it will bring a good trade-in value if and when you want something better later; home-built jobs are rarely accepted as trade-ins."

"Here's another appreach . . . the second

hand market. Many hams who have started with modest gear eventually trade it in for something more elaborate or sell it at a substantial reduction. If of reliable make and it's appearance indicates that it has received reasonably good care, these can often be had for half or less than their original cost. Don't buy a 'pig in a poke' though: most hams are truthful and trustworthy in deals of this kind but are often prejudiced as they have used the equipment for some time, are used to it's little idiosyncrasies and can handle it; a green buyer however could experience rather unsatisfactory results. By all means arrange to try out a piece of gear like this if you're considering buying it and preferably have a more experienced ham look it over and try it out . . . be guided by his opinion. Larry or I will gladly do this for you . . . many of your fellow club members would also be helpful here too, if you find something you think is a good buy. Some of the mail order houses too, offer used equipment which they have taken on trade-ins and have had re-conditioned by their own technicians. World Radio Laboratories is one who specialize in this; there are a number of other reliable sources and vou'll find them advertised in the ham magazines".

"Another good bet in shopping for a receiver is the military surplus offerings. Stores specializing in this as well as many mail order firms who advertise, still have a considerable amount of this kind of gear around at unbelievably low cost when you consider what fine pieces of gear they offer. Again you should rely on an experienced ham in helping you choose something which you won't have to modify extensively for ham

band use."

Right here, Joe broke in with, "Say, FN, a couple of years ago when I was doing a lot of short-wave listening, I picked up a surplus BC-312-N receiver down at Jim Turners' for thirty-five bucks. It sure is a well-built deal and really brings in short-wave broadcasts from all over the world. I often hear amateur radio phones at certain places on the dial and the thing is just *loaded* with all kinds of code signals but I don't know who they are. Could I use this receiver for my novice station?"

"You sure can Joe and it's a dandy; I used one for several years before I got this little Davco solid state job I'm using now. The BC-312 is built like a battleship and

is plenty sensitive and selective to pull ir ham signals from all over the world and you'll find it will fill the bill for you for a long time to come, right on into your general class operation. Only high frequency novice ham band you won't find on it is the 15 meter spread; the BC-312 covers the 20, 40, 80 and even the 160 meter bands in fine shape. When you reach the point where you think you'd like to play around on 15, you can build a simple converter to extend the range of the BC-312 into this band. So, you're all fixed with a receiver for a long time to come . . . how about you Judy?"

"Oh, I'm not so lucky I guess; Dad's got some kind of an FM rig but it's no good for ham bands so I'll have to start from scratch" she replied. "Anyway I've saved a little money this summer from picking berries and a bit of baby-sitting so I guess

thats' a good way to spend it".

Larry chimed in with a suggestion that maybe Judy and Joe could take a look down at Jim Turner's and see what he might have in the way of a good surplus military re-

ceiver or a second hand ham job.

"If you kids turn up something that looks good, I'll be glad to take a look at it and check it over for you. Jim will let you take it home and try it for a few days Judy, I know." Both kids agreed to do a bit of window shopping at Jim's place and the other two electronic stores in town and made a date for the 'great adventure' for the following week.

With the receiver situation pretty well in hand now, FN suggested, "Let's call it quits for today then . . . it's about lunch time for all hands anyway. You young 'uns be out here two weeks from today, sharp at nine a. m. and we'll put you through your code exam. Don't forget now, write a postcard to the FCC and ask for your amateur radio operator license application forms, soon as you get home. Don't put it off or you may not get 'em in time . . . remember, FCC's mail basket is piled mountain high!"

"OK Gramps" Judy replied, "we'll do it" and at Larrys invitation, they tied her bike on his rear bumper and she climbed in with him for the short ride home while Joe kicked the Honda starter and took off after a friendly wave and an exchange of the now familiar "73" . . BCNU . ."

Going RTTY: Part Four

Frequency Shift Keying

The terminal unit is complete with its scope monitor and you have been getting fine copy.

Now you desire to put a RTTY signal on the air and the question is—how?

Let's first take another look at the terminal unit circuit described in December 73 (1964), and add the mercury wetted keying relay.

The addition to the circuit is the dotted lines in Fig. 1, and only the section of the original circuit covering the 6AQ5 is shown.

This relay will permit you to key the transmitter through the keyboard of your machine, since depressing the keys on the machine will open the loop current and permit the relay to key the frequency shift keying circuit of the transmitter, and at the same time produce local copy on your machine.

The mercury wetted relay shown is the WE276, although others will work as well, with the required socket changes.

The only word of caution is that the mercury wetted relay must be mounted in a vertical position.

Now that the modification is completed, let's look first to the use of frequency shift keying and a simple way of accomplishing it on the average transmitter.

Let's see what we mean by frequency shift keying, assuming that we will employ the standard shift of 850 Hz.

The terms applied to this difference in

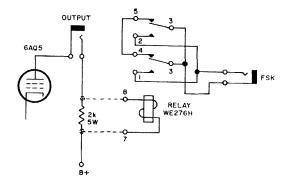

Fig. 1. Adding a keying relay to the terminal unit described in the December 1964 73.

frequency are MARK and SPACE, the first being the RF carrier and the difference in this MARK and the capacity introduced into the cathode circuit of the BFO, is called the SPACE signal.

To illustrate, let's take a frequency of 7137 kHz. This would be the MARK signal. Now to shift this signal down 850 Hz would produce a SPACE signal of 7136.150 kHz.

Now how do we accomplish the change in our MARK signal or the fundamental frequency of our transmitter?

Fig. 2 shows a simple circuit which can be used with most transmitters and others with certain modification, but the principle of creating the frequency shift remains the same.

What occurs is that additional capacity is placed across the LC circuit of the oscillator, which lowers the oscillator frequency sufficiently to move the transmitter carrier frequency 850 Hz.

It should be pointed out that the MARK signal is always the higher of the two frequencies, so that the SPACE signal is shifted downward in frequency 850 Hz.

The slug tuned coil (B) is made of 15-20 turns of about 22 wire on a ½ inch form and tuned to an inductance of about 40 mH. If you are unable to reach the 850 Hz between the MARK and SPACE signal, vary the slug in a (B) slightly.

In adjusting the shift pot it must be done slowly, observing the scope monitor for full deflection on both MARK and SPACE. A little experimenting with this adjustment will make for a 850-Hz setting.

A Solid-State Product Detector

Improve the performance of your receiver on SSB and CW with this simple transistor product detector.

All receivers not specifically designed for SSB reception suffer, to some extent, in quality and ease of tuning when used for this mode. Distortion of the received signal occurs for a number of reasons. When this includes BFO pulling, reduction of the rf gain may prove necessary. This in turn leads to loss of sensitivity and does not allow the AGC system to operate effectively. This is a less than satisfactory state of affairs.

With the advent of SSB and the almost total disappearance of AM from the HF amateur bands, good SSB reception is mandatory. To date, a combination of hang-AGC and a product detector seems to be the best solution. The product detector is the most important element of this pair and numerous articles have appeared discussing vacuum tube versions of this worthy circuit. There has been very little information dealing with the design of a solid-state version, however.

This article will describe a design which is a transistor equivalent of the popular dual-triode product detector. It will discuss the causes of distortion to SSB signals which include BFO instability as a result of pulling, AGC non-linearity and inter-modulation distortion. As an example of these problems and their cure, it will refer to a product detector built for the Heathkit "Mohican".

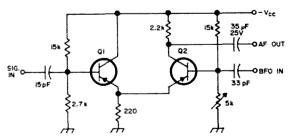

Fig. 1. Schematic of WB6CHQ's simple product detector. The transistors are not critical; IR TR-06's were used in the author's version, which was installed in a Heath Mohican.

In the GC-1A, the primary cause of distortion to SSB signals is BFO pulling. This phenomenon is the direct result of the presence of strong signals in the BFO circuit. In this receiver, the BFO output is injected at the input of the third if amplifier. This is done by connecting a 4.7-pf capacitor from the collector of the second if to a tap on the BFO inductor. Thus, any signal in the if strip is also in the tuned circuit of the BFO to some degree.

To understand why this will pull an oscillator, consider The tuned-grid, tuned-plate oscillator. It may be shown that in this oscillator, the tuned circuit with the higher "Q" will control the frequency. This is so because, a low "Q" tuned circuit having a broader frequency response, more feedback will be provided to the high "Q" circuit. Since feedback is the essence of oscillation, the tuned circuit getting the most feedback will control the frequency of oscillation.

By applying this logic to the BFO, it is easy to see how pulling occurs. If the BFO is treated as if it were a TGTP oscillator, then the incoming signal can be thought of as a tuned circuit with infinite "Q". With this situation the closer BFO gets to the signal frequency, or vice-versa, than, of the two feedbacks present, that from the signal and that from the BFO itself, the more predominate the signal becomes. At some point in tuning, it becomes the controlling feedback and the BFO shifts abruptly to the signal frequency.

When this occurs, the frequency difference between the signal and BFO is necessarily zero. Since the desired audio output is that frequency difference, there can be no audio output. With an SSB signal, the peaks will be strong enough to pull the BFO leaving only the lower amplitude portions of the signal as output. The result is a highly punctuated garble.

With a diode detector, an output of a different but still useless nature is possible. A diode is a non-linear impedance, that is, the impedance varies as a function of the applied voltage or current. A fundamental principle of electronics states that an AC signal applied to a non-linear impedance will generate harmonics of itself. If two frequencies are applied simultaneously, they will also generate their sum and difference frequencies. When a signal as complex as an SSB signal meets a diode, the result is only slightly less calamitous than the famous meeting of the irresistable force-and the immovable object. In this situation, every audio component present may mix with every other audio component to form still more audio components. The result is the muffled, quacking, semi-speech with which we have become familiar with the rising popularity of SSB.

These components are also the output when the BFO locks onto one of the frequencies of an SSB signal. But even if the BFO stays where it should, these components are still present in the output of the diode mixer, because the diode must mix all frequency components present. This is where the product detector has a distinct advantage. It can mix only BFO and signal, rather than BFO and signal, signal and signal, etc. This type of distortion will be recognizable to hi-fi fans as inter-modulation distortion.

The AGC in a receiver can be another source of distortion. In receivers such as the GC-1A, AGC response is fairly fast, capable of following the syllabic rate of an SSB signal or the keying of fast CW. With a perfectly linear AGC, the only effect on an SSB signal will be uniform compression, or overall reduction of the dynamic range. If, however, the AGC response is not linear (which is likely since no tube or transistor has an infinite dynamic range, then the result will be envelope distrotion. This is a rearrangement of the relative amplitudes of the signal components. Normally, this distortion is not too severe as most signals will stay mainly within the most linear portion of the AGC response.

The more important problem with AGC is that, even without modification, it cannot be used effectively. If pulling occurs even with AGC, the AGC is not limiting the signal sufficiently and the only recourse is to reduce the RF gain. When this is done, the AGC begins to lose control and its advant-

ages are gone. It is worth noting that for the GC-1A, Heath recommends that it be turned off for SSB reception.

Theory

The product detector offers a solution to most of these problems. It allows far better isolation for the BFO, reducing pulling to a bare minimum. Being a linear device, it does not experience the extreme inter-modulation distortion possible with a diode detector. Finally, since pulling is not a problem, it allows operation of the receiver at maximum rf gain and use of the AGC. Thus, neither the convenience of AGC nor the receivers sensitivity are sacrificed to the "new wave".

The product detector is more properly known as a multiplicative mixer, the same circuit as is used for a converter in the front end of most modern receivers. This fact will explain the product detector circuits frequently seen which employ a pentagrid converter tube. Another apt name is "audio converter".

To see why and how a product detector works, refer to the circuit of Fig. 1. First, note that the coupling capacitors used have a very high reactance for transistor work, even at 455 kHz. The reactance of the 15-pF capacitor is about 20 kohm and that of the 33 pF is about half that. These high impedances are in series with the low input impedances of the transistors, providing a large voltage division. This insures small signal operation of the transistors guaranteeing their linearity.

This also provides a high degree of isolation for the BFO, which combined with the isolation inherent in the transistor, makes the BFO far more immune to pulling. This immunity is such that in the GC-1A, a local broadcast station about a mile distant, will not pull the oscillator more than about 50 Hz

In operation, Q1 is an emitter follower, whose vacuum tube corollary is the cathode follower. The same conditions hold true for both. They are capable of power gain, but not voltage gain. Since the emitter resistor is common to the emitter of both transistors, the signal is directly coupled to what is to it, a common-base amplifier. In this amplifier, voltage gain is dependent to a certain extent on the quiescent or operating point of the transistor. This operating point is a function of biasing and the bias may be controlled at the base.

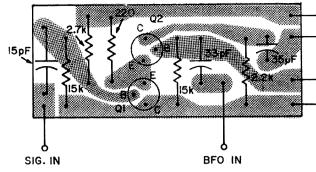

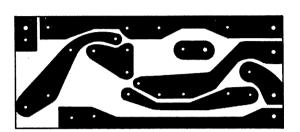

Fig. 2. Layout for the etched circuit board used by WB6CHQ.

Since the BFO is connected to the base of Q2, it is constantly changing the bias and, therefore, the quiescent point at a rate near the frequency of the signal on the emitter. This means that the signal sees a linear input impedance and a rapidly changing voltage gain. This is the reason for the term, 'multiplicative'. Since the output voltage is the input voltage multiplied by the voltage gain, if we must inleude the BFO frequency to express the voltage gain in the equation, then the effect is literally multiplicative mixing.

Adjustment and operation:

This circuit is sufficiently simple that its construction should provide no obstacle to anyone. I have included the PC board layout (Fig. 2) that I used and one can see that I followed the actual appearance of the schematic quite closely. If you wish to make your own layout, this is generally the best method to follow, at least for the smaller projects. I strongly recommend that a PC board be used. They provide the neatest, most compact, best appearing and most durable form of construction available for small circuits such as this. Etching is not difficult and kits are available for it.

Having constructed the circuit, it should be mounted in the receiver and connections made to it. The supply voltage may range from six to twelve volts but be sure that you do not exceed the collector breakdown ratings of the transistor you use. The BFO should be able to supply about .2 volts RMS to the base of Q2 and the signal should not exceed this value at the base of Q1. These values are valid for the circuit when it is correctly adjusted.

o – V_{cc} •5k POT

OAF OUT

OGND

To adjust the product detector, first set the linearity pot to zero resistance (so that the base of Q2 is shorted to ground). With the BFO off, (making sure that the product detector is on adjust the linearity pot from zero until the signal to which your are tuned becomes slightly audible with the volume control on full. A local broadcast station makes an excellent test signal. When the BFO is turned on the signal should be very loud, though not quite as loud as with the diode detector for an AM signal. This will vary with the type of receiver but will probably hold true in most cases. If one wishes to tinker further, the ultimate desired result is a maximum of signal with the BFO on and minimum with it off. The signal present when the BFO is off is a result of intermodulation distortion and is not desired for best reception.

When all this accomplished, it is possible that the BFO will need adjustment to get a zero-beat at the zero-beat mark on its control. In the GC-1A, this is remedied by tuning an AM signal for maximum on the S-meter, setting the BFO at the zero mark, and adjusting the BFO inductor for a zero-beat. Similar methods may be used for any receiver.

In operation, the product detector is virtually identical to the diode detector with the major difference being the improved reception. The BFO is adjusted to one or the other side of zero-beat depending on which sideband is wanted. The signal should show the most deflection on the S-meter when the voice sounds the best. The receiver may be tuned with the RF gain on full and the AGC on.

The ideal SSB receiver is the one on which the only adjustment required is the tuning and sideband selection. When this product detector is used in the GC-1A or any other receiver, operation begins to approach that ideal.

AMCOM—

Amateur Mobile Communications

The Phil-Mont Mobile Radio Club, Inc. of Philadelphia and vicinity is endeavoring to complete the outfitting of what it considers a communications facility second to none in AMCOM, Amateur Mobile COMmunications. This is being accomplished through the equipping of an independently powered mobile communications trailer, W3RQZ/portable, with its own prime mover also fully equipped to operate as an independent mobile relay station, W3RQZ/mobile.

Photo 1 shows the com-truck, a 1949 International Metro, and the com-trailer made by the Schulte Company in 1953. The truck was obtained from the Township of Springfield, Delaware County, Pennsylvania, as a former bookmobile. It is now painted a bright emergency red, and well-marked as W3RQZ, Mobile Communications Center. It is well-known to Phil-Monters as the "Red Truck." The trailer was purchased from a contractor whose use necessitated minor body repair topped off with Rustoleum silver paint.

The emergency Red Truck contains equipment mainly for 10 meter AM operation, a 60-watt unit with VFO and tunable receiver,

and a 30-watt fixed frequency unit for operation on the club frequency of 29.493 MHz. This unit can be operated at its position or by the driver of the vehicle. AC power can be supplied by an external generator hauled in the truck. DC power is supplied by a 100-ampere Leece-Neville generating system.

Two other operating positions are available for 2 meter and 6 meter Gonset Communicators, with ac and dc power cords installed. The units are not permanently mounted in the truck, but are available from club members at a moment's notice.

Also included are two telephone line inputs for local and common battery lines; 25 watt public address system which operates on 6 Vdc or 110 Vac; automatic change over for lighting from ac to dc; metering of generator voltage, frequency and running time; handi-talkies on 29.493 MHz; galley supplies; vehicle and other tools; and local area maps. Antennas are available for all equipment, and are mounted in positions for minimum interference between bands.

The communications trailer is Phil-Mont's most refined piece of emergency equipment.

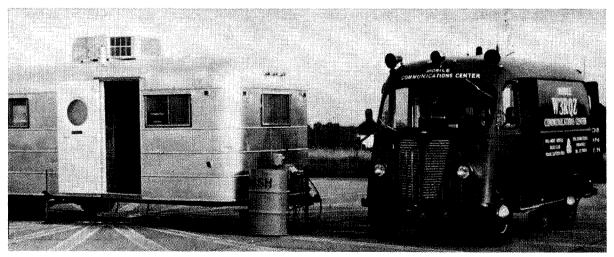

Photo I. The Phil-Mont mobile communications vehicles. On the left is the communications trailer, and on the right, the Red Truck.

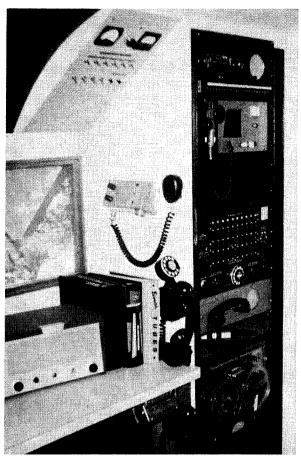

Photo 2. The message center position in the trailer.

Twenty-six feet long, it is divided into an operating area 7' by 14' and a lounge area 7' by 12'.

The operating area walls and ceiling are lined with accoustical tile and are fiber glass insulated. All interiors are white for light reflection, with dark green kick areas. Wall to wall carpeting completes the noise reduction. The lounge area includes a daybed for overnight operators, galley supplies for coffee breaks, and storage cabinets for galley and stationery supplies. The lounge floor is tiled for easy cleaning. Each area has its own door, and eight windows around the trailer provide adequate ventilation when the 1½ ton air-conditioner is not in use.

W3RQZ/portable consists of seven operating positions coordinated by a Message Center Chief. Stationed by the equipment rack at the door between the lounge and operating areas, the Message Center Chief accepts all incoming traffic originating at the portable operating site. He distributes the traffic to the proper operating position for transmission and keeps track of its progress. From his position he has the capability of monitoring, recording or placing on public

address both sides of any or all QSO's in progress. He can also patch any receiver to any push-to-talk transmitter.

On the ceiling to the left of the rack is a power panel which distributes the power to the equipment, lights, and fans. It also provides complete instrumentation of the voltage, current, frequency, and running time of the incoming power.

In the rack, from top to bottom, are: broadcast band monitor; NARCO VGTR-2 for use on aircraft frequencies in emergency situations; message center patching and monitoring equipment; tape recorder; and

public address amplifier.

On the side of the rack is a control-head for 6 meter FM with an RCA CMV-3 on 52.525 MHz and a telephone instrument for use with two incoming lines. Seen on and under the table are speakers and controls for several safety service receivers on both high and lowband police and fire frequencies. The binders contain complete schematics for all equipment.

Photo 3 is a view from the message center position toward the rear of the trailer. In it can be seen an SB-33 for 75, 40, and 20 meter sideband; a 6 meter AM unit; and at the 10 meter position on the extreme right, an Elmac AF-67 and PMR-6. Either microphones and earphones or operator headsets are used with floor switches for maximum noise reduction and operating ease.

Not shown is a Gonset Communicator II, modified for push-to-talk, and a Model 15 Teletype for future use on 80 meter and 40 meter FSK or 6 meter and 2 meter AFSK.

Vertical antennas are available permanently attached for all frequencies but those below 14 MHz. For such frequencies coilloaded mobile whips or portable wire-antennas are used.

Before the acquisition of the com-trailer,

Photo 3. View toward trailer rear from the message center position.

Phil-Mont hauled portable power behind the Red Truck in a generator trailer constructed by club members. This trailer houses a 3 kW-110 volt Onan generator, Model W2C, water-cooled, two cylinder-four cycle, with electric start and ignition. The generator trailer is completely enclosed and has louvered access doors; power cords, junction boxes, jacks, wheel chocks, gas cans, and a power distribution panel complete the installation. This unit is up for sale, but is hauled by other vehicles for present communications projects in the absence of a new Onan Model 305CCK, to be purchased by the club when funds permit. The new Onan will use propane as fuel and will be stored in the Red Truck or any other vehicle used to tow the com-trailer.

Phil-Mont is available with its two vehicles to undertake any communications activity, be it an emergency or a routine project. With a force of Phil-Monters active daily in their own mobiles on 29.493 MHz AM, 52.525 MHz FM, and 3.995 MHz SSB, practice in mobile communications is continual, and leads them to say that Phil-Mont in ready "every single minute."

Inquiries on particulars concerning Phil-Mont's vehicles should be addressed to W3QQH, C. R. Spencer, Jr., 124 Central Avenue, North Hills, Pennsylvania 19038.

Improving the Ham M

I am of the firm opinion that the Ham-M is the finest commercial rotator made . . . mechanically. It is very ruggedly built and, when properly installed, will not be the limiting factor, strength-wise, in any reasonable antenna installation.

My complaint is with the direction indicating circuit. The meter in the control box is calibrated in 5° increments. And the signal which the meter measures is the output of a low impedance voltage divider consiting of a wire-wound pot located in the rotor housing. What could be more accurate?

The catch is simply that the bridge is driven by a dc voltage which is rectified from the ac line through a transformer and is directly proportional to it. What this means is that on a cold day when everyone is using their electric heaters, causing the line voltage to drop, my meter says that the antenna is pointed more to the west that on a "warm" day. Or, since I have poor

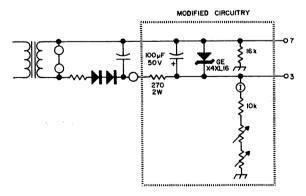

Fig. 1. Circuit of the Ham M control box as modified for consistent directional readings.

line voltage regulation in the shack, whenever I talk the linear up, the direction meter dips to the west.

A moment of head scratching convinced me that this nasty problem should be solved with only the most advanced techniques: a zener diode was called for, to regulate the indicator supply.

A zener diode, you may recall, is the solid-state design engineer's answer to the VR tube. These little gadgets can regulate a voltage with a dynamic impedance of as low as 1Ω or less, far better than a VR tube. They come in lower voltages and a wider range, too. And this is the turning point of the story.

The cover of the control box was removed, the zener diode and the three new parts shown in Fig. 1 were installed and the cover was replaced. A word of caution is in order about the installation of the zener diode. It should be connected "backward", that is, with the cathode wired to the positive line. Connecting the diode incorrectly can not harm anything. The only result will be that the output voltage will be less than a volt instead of 16 volts. The usual caution should be exercised with the electrolytic capacitor.

The results have been most satisfactory. During more than eighteen months of operation, the full scale voltage of the bridge has been checked periodically and found to be right on the nose. And even better—when I talk the linear up, the direction meter doesn't budge a bit.

The Classic Feed System

By W. E. "BARNEY" ST. VRAIN, WØPXE

DESIGNING ENGINEER - CLASSIC 33 PROJECT MOSLEY ELECTRONICS, INCORPORATED 4610 N. Lindbergh Blvd., Bridgeton, Mo. 63042.

Code 107

beams several years ago, the method of feeding such antennas has been a subject of much disagreement. When these antennas were introduced a few years ago, Mosley Electronics ran a series of advertisements in the technical magazines explaining the method used on our Trap-Master and Power-Master series. Since that time we have tried a wide variety of feed systems endeavoring to improve on the original system.

Testing Other Feed Systems

In testing, we found a three band gamma system ineffective without isolation networks which resulted in the feed system costing about equal to the antenna cost; system using hairpins, the cost proved low but did not provide a better match than the original Mosley matching system. It became quite clear to us, the Mosley system was hard to beat, for we had found only one slight disadvantage, the elements needed to be stagger tuned to raise the feed point resistance from about 30 to 50 ohms. This slight detuning, which proved advantageous in increasing the bandwidth, brought about, in turn, a slight gain loss of about 0.5 to 1.0 db. at resonance.

The Classic-33 System

In order to give hams a new choice in beam matching systems and an antenna featuring maximum gain with increased bandwidth, we devised the matching method used on our New Classic 33 antenna, a method which takes advantage of the principle that antenna resistance at the center driving point increases as the antenna length increases. Figure No. 1 shows the radiator element of a three element beam at resonance having an impedance at the driving point (Z_A) of about 30 + JO ohms. If the element is made longer, Z_A can be raised to about 50 + J50 ohms. (Figure No. 2) Since the reactance is inductive, it can be canceled with a series capacitor of 50 ohms reactance, leaving 50 ohms

feed point resistance. (Figure No. 3) Series capacitors used on the Classic 33 are made by inserting a suitable length of heavily insulated wire into each half of the element tube at the center. The wires are terminated in a plastic tube enclosure with a type "N" connector for connection of the coaxial cable. To isolate the outer coax conductor from ground, the coax line is coiled for a few turns near the antenna end. This is designed to prevent the very unlikely affect of "Feed Line Radiation".

Fig. 1.
$$L = \frac{\lambda}{2} \qquad Z_A = 30 + j_0$$

Fig. 2.

$$L = \frac{\lambda}{2} + Z_A = 50 + \dot{J}50$$

Fig. 3.
$$Z_{A} = 50 + j_{0}$$

Converting Other Beams

This feed system could feasibly be used on our other Trap-Master beams, but little would be gained and the antenna would need to be completely rebuilt. The big difference between the new Trap-Master beam and the TA-33 is that the latter has conversion features, while the Classic 33 does not. The engineers at Mosley designed the Classic 33 to give the ham a little extra gain on all bands. It is our conviction that discriminating DX'ers will find this new tri bander specifically suited to their needs, but hams buying the well-known TA-33 will still enjoy a superior quality DX antenna with a gain very close to that of the Classic 33.

The Slide Rule Made Easy

The slide rule is a great timesaver for anyone who needs to make a lot of calculations. Here's a simple course in using one.

Are you interested in improving your personal capabilities? Have you given any thought toward mastering the use of a slide rule? Did you, at one time, purchase a slide rule and then fail to follow through on learning how to use it? If the answer to any of these questions is yes, then here is your opportunity to get started on a simple, worthwhile project.

Radio amateurs who are engineering or mathematic students, radio amateurs taking electronic or mechanical refresher courses, and radio amateurs in the electronic, electrical, or mechanical engineering professions readily realize the value of knowing how to use a slide rule. Radio amateurs who design their own equipment will find the slide rule to be an ideal timesaver when they become involved in mathematical processes.

The person who does not use a slide rule for calculations is far less efficient than the person who does use one. For instance, without a slide rule, problems must be written out and the operations performed in lengthy detail by using the rules of ordinary arithmetic. This is very time consuming and the chance of making errors is very high. Sometimes a problem spreads over such a large area that the real point of the problem is lost. Technical people find it to their advantage to be proficient in the use of a slide rule as every practical problem which requires a concrete answer will reduce to a mathematical computation. They find a great deal of time being saved while performing operations in multiplication, division, square roots, etc., on a slide rule and with a fairly high degree of accuracy.

General

What is a slide rule? It is a tool, or an instrument, designed to save time and labor for a person who is performing mathematical calculations. It is the mechanical equivalent

of a table of logarithms. It is a ruler, a type of measuring stick which contains a number of graduated scales arranged in such a manner that multiplication, division, squaring, cubing, extracting roots, and other operations may be performed easily by the manipulation of the rule and the reading of the indications obtained on the scales.

There are several types of slide rules available, and before purchasing one, the user should investigate further as to which one is best suited to his needs or purposes. Your technical associates, or instructor, can advise you as to which one will best satisfy your need. It is better to be advised in advance than to find out later that you possess a slide rule not satisfactory for your purposes. If you don't want to take advice, check a catalog and you will find at least five kinds of slide rules available. Your own judgment may lead you to purchase a rule which is used by physicists or someone above the scope of your purpose. There are trig rules and beginners' rules. There are 5-inch rules, 10-inch rules, and circular rules. So, be careful before you decide which rule to purchase. The vectorlog rule has 27 scales and is generally used to solve problems in electrical engineering physics. The dynamic reactance rule is used in calculations for decibel, inductive reactance, capacitive reactance, resonant frequency, surge impedance, etc. The log log dupli-decimal trigonometric rule has 21 scales including five log log scales and is used extensively when working with logarithms. A trig rule is usually satisfactory for most general amateur calculations, but working with advanced ac theory will require the use of a log log rule.

Complete text books on the use of a slide rule are available and instruction books accompany most new slide rules. This article includes condensed and simplified instructions for the fundamental and basic uses of a

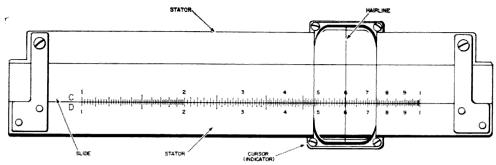

Fig. 1. The major parts of a slide rule with the two most basic scales, the C and D scales.

slide rule and should be beneficial to a beginner.

Slide rule computations for use in electronics are usually more accurate than the tolerances of the circuit components involved. A ten-inch slide rule will give results accurate to within one part in 1000, or one-tenth of one percent when used correctly. As a point of comparison, a good ohmmeter has an accuracy of ± 2 percent and this will lead us to assume that for all practical amateur purposes, numbers used in slide rule calculations may be rounded off to a value which can be easily handled (significant figures).

When working out problems involving ultra-high radio frequencies, the decimal point and powers of ten become involved. A person possessing a good knowledge of working with the powers of ten will have no difficulty in properly placing a decimal point when using a slide rule.

You have now been introduced to the slide rule and it is necessary that you possess a slide rule in order to benefit fully from the remainder of this article, though Fig. 1 illustrates the most common scales.

Construction of the slide rule

A slide rule has three major parts (see Fig. 1):

- (1) the indicator, or cursor
- (2) the slide
- (3) the stator (upper and lower bars) Each scale on the slide or stators is identified by a letter (A, B, C, C1, C1F, CF, D, DF, K, L. LLO, LLOO, LL1, LL2 LL3, S, ST, and T). There are two C, C1, and D scales so that the most commonly used scales will be available on either side of the rule. These scales are found on a log log rule and there will be fewer on a trig rule or on a beginners rule.

If the user learns how to read the scales, how to set the slide and the indicator for each operation to be performed, and how to place the decimal point in the answer, it will then be a simple matter to multiply and divide, to square a number or find the square root of a number, to cube a number or find the cube root of a number, to find the logarithm of a number or find a number whose logarithm is known, and to find the sine, cosine, or tangent of an angle or to find an angle whose sine, cosine, or tangent is known.

Interpreting the C and D scales

The C scale on the slide and the D scale on the stator are the scales most frequently used and are exactly alike. They are the fundamental scales of a slide rule and are used for all general fundamental calculations. Examine the D scale (Fig. 1) and you will see lines and large numerals printed on the stator (1, 2, 3, 4, 5, 6, 7, 8, 9). These lines are called primary graduations. The line labeled 1 at the right end of the C scale is called the right index, the line labeled 1 on the left end of the C scale is called the left index. The distance between 1 and 2 on the D scale is divided into 10 parts. These are called the secondary graduations (1, 2, 3, 4, 5, 6, 7, 8, 9). They are located between 1 and the primary graduation 2. To locate the numbers 12 and 8 on the D scale-8 is found at the primary graduation marked 8, 12 is found at the secondary graduation marked 2 (on the left). The number 14 is the secondary graduation marked 4 (on the left) and the number 19 is the secondary graduation marked 9 (on the left). The number 35 is found at the fifth secondary graduation to the right of primary graduation 3 (3.5 X 10). The number 87 is located at the seventh

secondary graduation to the right of primary graduation 8 (8.7 X 10). The increments of a secondary number are called tertiary graduations. For instance, on the D scale, the distance between 3 and 4 is divided into 50 graduations, each one having a value of 2. The number 3.6 is located 30 tertiary graduations to the right of primary graduation 3, or 6 secondary graduations to the right of primary graduation 3. The number 85.000 is located at the fifth secondary graduation (or the tenth tertiary graduation) to the right of primary graduation 8 (8.5 X 104). If you place the cursor hairline at secondary graduation 2 on the D scale, you will be reading the number 12 (.012, 1.2, 120, 1200, etc.). Place the cursor hairline at primary graduation 9 on the D scale, you will be reading the number 9 (.009, .09, .9, 90, 900, etc.).

Use of other scales

The DF and CF scales are the same as the D and C scales except that they are folded at π (3.14). To avoid the necessity of resetting when an answer runs off the scale, they are used with the C and D scales. The C1 scale is an inverted C scale used in reading the reciprocal of a number. The D1 scale is an inverted D scale the same as the C1 scale. The C1F scale is an inverted CF scale used with the DF scale in the same manner as the C1 scale is used with the D scale. The A and B scales are identical and are used with the C and D scales when finding squares and square roots. The K scale is used in finding cubes and cube roots. The S scale is used when working with the sine and cosine of an angle. The T scale is used when working with the tangent of an angle. Trig slide rules may have a T2 scale for working with tangents of angles greater than 45°. The ST scale is used when working with sines and cosines of angles less than 6°. The L scale is used with the D scale for finding the mantissas of the common logarithms.

Simple multiplication exercises

Get familiar with using the slide rule by calculating simple problems first. The easiest function to perform first is the multiplication of two numbers. Set the left index 1 on the C scale (slide) to line up with the primary graduation 2 on the D scale. Move the cursor hairline to the primary graduation 2 on the C scale and read the result

(2 X 2) on the D scale as being the number 4 (20 X 2 = 40, 20 X 20 = 400, 2000 X 2000 = 4,000,000, .02 X .2 = .0004, etc.). Set the right index 1 on the C scale (slide) to line up with the primary graduation 8 on the D scale. Move the cursor hairline to the primary graduation 7 on the C scale and read the result (8 X 7) on the D scale as being the number 56 (.8 X .7 = .56, 80 X 70 = 5600, .08 X .07 = .0056, 800 X 700 = 560,000, etc.).

Simple division exercise

Division of numbers on a slide rule is the opposite or inverse operation of multiplication. To divide 8 by 4, move the C scale (slide) until 4 is lined up with 8 on the D scale and read the result (8/4) found at the left index point on the D scale as being 2 (.08/.4 = .2, 800/.004 = 2000,000, etc.)

Multiplication of three numbers

Multiplication of three numbers is a little more involved than with two numbers, but is not complicated. Multiply 28.5 X 4.6 X 6 as follows: make an approximation—30 times 4 times 6 = 720. Set the right index 1 of the C scale to line up with 2.85 on the D scale. Set the cursor hairline at 4.6 on the C scale. Set the left index 1 of the C scale under the hairline. Read the result on the D scale directly below 6 on the C scale as 790. Practice will improve your accuracy.

Multiplication and division combined

Find the product of two numbers and divide the result by a nother number. $Try = \frac{24 \times 38}{12.4}$ An approximate answer could be 8. Set 12.4 on the C scale to line up with 2.4 on the D scale. Move the cursor hairline to 3.8 on the C scale and read the result on the D scale as 7.35.

Simple proportion exercises

Here is the easy way to find proportions. Find x if 2/3=5/x. Place 2 on the C scale directly over 3 on the D scale. Move the cursor hairline to 5 on the C scale and read the result on the D scale as 7.5. Find x if 18/x = 3.5/22. Place 3.5 on the C scale directly over 22 on the D scale. Set the cursor hairline to 18 on the C scale and

read the result on the D scale as 113.

Circular measure exercises

Convert $\pi/2$ radians to degrees. Set 2 on the C scale directly over the π mark on the D scale. Move the cursor hairline over the left index 1 on the C scale and read the answer on the D scale as being 1.57 degrees. Convert 45° to radians. Place R (or P°) on the C scale directly over 4.5 on the D scale. Read the result on the D scale directly below the right index 1 of the C scale as .785. We know it will be less than 1 because 1 radian is equal to 57.3 degrees.

Simple trigonometry exercises

It is very easy to calculate circle circumference and diameter. Here we use the D and DF scales. Find the circumference of a circle having a diameter of 4 cm. Place the cursor hairline at 4 on the D scale and read the result on the DF scale—12.57 cm. Find the diameter of a circle having a circumference of 50 cm. Place the cursor hairline at 5 on the DF scale and read the result on the D scale—15.8 cm.

Squaring and square or cube roots

Likewise, squaring numbers and extracting square roots turns out to be very easy. To square the number 3.3, set the cursor hairline to 3.3 on the D scale and read the result on the A scale-10.9. Find the square root of 40. Set the cursor hairline to 40 on the A scale and read the result on the D scale-6.3. The K scale is set up in three sections. Use the left section for finding the cube root of numbers between 1 and 10, the middle section for finding the cube root of numbers between 10 and 100, and the right section for finding the cube root of numbers between 100 and 1000. Find the cube root of 8. Set the cursor hairline to 8 on the left section of the K scale, read 2 on the D scale. Find the cube root of 80. Set the cursor hairline to 8 on the middle section of the K scale, read 4.3 on the D scale. Find the cube root of 800. Set the cursor hairline to 8 on the right section of the K scale, read 9.3 on the D scale.

Logarithm exercises

A slide rule reads only the mantissa of

common logarithms and the characteristic is to be calculated. Find log₁₀ 3.14. Place the cursor hairline at 3.14 on the D scale. Read the result on the L scale directly under the hairline as 0.497. Find log₁₀ 887. Place the cursor hairline at 8.87 on the D scale. Read 0.948 on the L scale. Add the characteristic 2 and the answer is 2.948.

Working with the trigonometric functions

Trigonometric functions are readily determined by the use of a slide rule. Working with these functions involves the use of the C, C1, D, S, T, and ST scales. Examination of the S, T, and ST scales shows each identified graduation as having a double set of numbered graduations. On the S scale, which will be used with the C or D scale, the left hand (black) graduations are/angles between 5.7° and 90° to be used with sine value calculations. The right hand (red) graduations are angles between 5.7° and 84° to be used with cosine value calculations. Find the sine of 15°. Set the cursor hairline to the black 15 on the S scale and read 0.259 on the D scale. Find the cosine of 60°. Set the cursor hairline to the red 60 on the S scale and read 0.5 on the D scale. If the sine value is 0.96, what is its angle? Set the cursor hairline to 9.6 on the D scale and read 74° on the S scale. On the T scale, the left hand (black) graduations are angles between 5.7° and 45° to be used with tangent value calculations. The right hand (red) graduations are angles between 45° and 84.3° to be used with cotangent value calculations. The tangents of angles between 5.7° and 45° are read on the C or D scale and those between 45° and 84.3° are read on the C1 scale. Cotangents of angles between 45° and 84.3° are read on the C or D scale and those between 5.7° and 45° are read on the C1 scale. Find the tangent of 31°. Set the cursor hairline to the black 31 on the T scale and read 0.6 on the C or D scale. Find the tangent of 70°. Set the cursor hairline to the red 70 on the T scale and read 2.75 on the C1 scale. The ST scale is used when working with sines and tangents of angles between 0.5° and 5.7°.

The author used a Lafayette 99-7031 10inch log log dupli trig slide rule in the above trig function manipulations. More detail could be given towards this type of coverage, but since not all slide rules are

! ADD PUNCH AND CLARITY TO YOUR SIGNAL!

- INSTANTANEOUS LIMITING ACTION
- NO APPRECIABLE DISTORTION
- COMPLETELY COMPATIBLE WITH SSB
- TALK POWER GAIN AT LEAST 10db
- OPTIMUM FREQUENCY RESPONSE
- INSTALLS IN MICROPHONE LEAD
- ALL SOLID STATE PRINTED CIRCUITRY

NEW

COMDEL SPEECH PROCESSOR MODEL CSP 11

A prototype of the CSP 11 has proved itself an effective communication aid on the amateur bands over several years. Its prominent feature is the instantaneous limiting action without the harmonic distortion which often makes the use of conventional speech clippers marginal, particularly with SSB transmitters. Designed for relatively insensitive high Z microphones—a gain control is provided—the unit will enhance the intelligibility of voice signals considerably under difficult conditions. "MIL" design and construction is employed throughout for high reliability and long life. Power is obtained from internal batteries (6 "D" cells—life exceeds 300 hours) or external source. Free brochure will be sent on request.

PRICE: \$111.00 POST PAID IN U.S.A. (Mass. residents add 3% tax)

COMDEL INC.—218 BAY ROAD—HAMILTON, MASS.—01982

alike, it would benefit the user more to study the examples given in the book which accompanies each new slide rule.

Log log scales

The LL scales on a log log rule represent a logarithm of a logarithm. The LL1, LL2, and LL3 scales range in values from 1.01 to 20,000, are used with the C and D scales, and give the natural logarithms of numbers greater than unity. The LLO and LLOO scales range in values from 0.0001 to .999, are used with the A and B scales, and give the natural logarithms of numbers less than unity.

Using the c, P° , and π gage marks

Near the left end of one C scale and near the end of one D scale you will note the small letter c. This represents 1.128 and is used when calculating the area of a circle. Find the area of a circle having a diameter of 1.4 cm. Set the cursor hairline to 1.4 on the D scale which does not have the letter c on it. Place the letter c on the C scale under the hairline. Move the cursor

hairline to the C scale left index. Turn the slide rule over and read the area on the A scale under the hairline as 1.53. The P° mark found on one of the C scales and on one of the D scales represent 5.72958 and is used when converting an angle from degrees to radians. The π mark found on the C, D, CF, and DF scales represents 3.1416 and is a ratio of the circumference of a circle to its diameter.

Conclusion

Much more could be written about the use of a slide rule but this article is presented with the hope of inducing amateurs to become familiar with the benefits to be gained by using a rule. More difficult exercises and information pertaining to the care and maintenance of a slide rule are usually contained in the book which accompanies a new slide rule. After some concentrated practice, one should be able to multiply, divide, handle square and cube roots, and some of the trig functions very easily. For those who wish to go further, it is recommended that they obtain a textbook covering all of the uses of a slide rule.

How to Make Better Panels

Do all of your construction projects seem to look horrible? Here are some good hints that will help you make them attractive.

What does your home made gear look like? If your work resembles much of mine, you may not be too eager to show it to the public eye. For some time I've used a simple ink-marking process on bare aluminum which is adequate but harsh and prone to glare. It was passable, but I felt persistently unhappy about its overall appearance. This article describes one of the ways I finally worked out for making more satisfactory panels.

You won't need any special tools or machinery. There are no chemical processes, although some time is required. The finished panels can be very colorful, and a few of mine are. Ten dollars should put you in business for the next two years or more, and the finished panels really do look good!

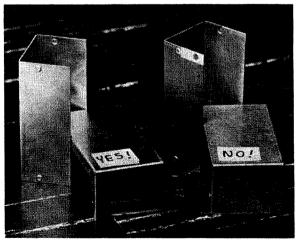

Materials Required

• 1. A scraping knife, a rather fine file, and some emery cloth.

These are the materials used in making panels. Most of them are very easily obtained from local hardware stores, supermarkets, and bookstores.

- 2. A sheet of fine grade wet sandpaper. A fine-textured abrasive on waterproof backing, used wet. The water prevents removed metal from building up little islands which clog the paper. Try some dry and see.
- 3. Kitchen detergent, stronger varieties preferred.
 - 4. Denim rag.
- 5. Large cardboard box and some cheesecloth, scotch tape and safety pins.
- 6. A few odd pieces of brick, wood, or pipe.
- 7. Rustoleum spray enamel, about \$2.00 per can. Their + 975 gray is good to start, and you might like to purchase other light colors later.
- 8. Draftsman's lettering supplies: ruler, pens, and waterproof India ink.
 - 9. Rustoleum #717 clear spray enamel.
 Purchase emery cloth and wet sandpaper

Choose unpainted metal parts for construction, and save yourself the trouble of cleaning off the manufacturer's inexpensive soft paint.

Simple spray booth. Maybe ten cents in materials. Store it front down to keep dust out.

which feels abrasive but not toothy to the touch. Different manufacturers use different grading systems so I haven't recommended a particular degree of roughness. Since you're not going to really lean on it, the scratches won't be deep and the grade you use is not critical.

Preparation

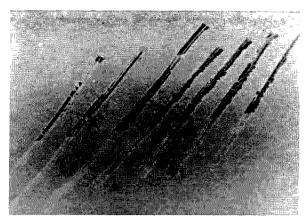

If you want a good job, the surface to be painted must be *real* clean. You have two foes: grease and dust. Grease spoils paint adhesion, and dust results in a relatively huge mound in the finish for each tiny particle. I hope you'll begin by practicing on some scrap metall

Surface preparation starts with the purchase of the chassis or panel that is to be painted. Choose aluminum with a natural or unpainted finish. This saves solvent problems or a trip there and elsewhere for somebody who can get it off for you.

You can make guide scratches on the panel surface during construction. But they mustn't be deep! Although I've never tried it, I suspect a good epoxy auto body filler could fill in some pretty deep gouges. An ordinary nail is hard enough to take a good point for working on soft aluminum, and will not need frequent resharpening.

When the construction work is done, go back over the chassis or panel to clean up the edges, corners and holes. A good knife, used carefully, will pare out the rough edges that usually appear around holes. A fine file can round off sharp corners and feather edges left by dull shearing tools. You may want to give the work a first finishing from a small piece of emery cloth.

Then make up a strong detergent solution and wash the work thoroughly. Use a

This piece of scrap metal was cleaned over all and then sanded on the upper portion only, before painting. Test scratches made with the edge of a sharp knife show good adhesion on the sanded part.

wad of denim as a washcloth, and scrub all surfaces twice, whether they get paint or not. This removes grease which could be carried around to the painted surface just ahead of the enamel. Rinse thoroughly, and by now your hands should be very clean too.

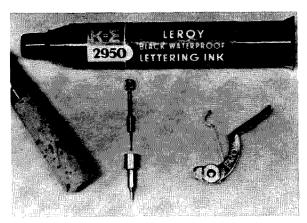

Still using warm water, have a go with wet sandpaper at the surfaces to be painted. Use only moderate pressure. Rub up and down, diagonally, crosswise, and in circular directions. The surface should take on a dull whitish-metallic sheen with no strongly preferred direction of marking. The enamel sticks very well to metal surfaces treated in this way, so that no primer is required. I've tried it both ways.

When you're done with this, shake off the excess water, wipe with clean paper towels, and put the work in a warm place to evaporate the last traces of moisture. When dry, wrap it in a clean newspaper and you can store it without deterioration of the surface.

If you're in a hurry, you can shortcut the following process by marking directly on the cleaned surface with India ink. Then spray clear enamel over all. Or you can apply clear fingernail polish over the labels and have your work back on the assembly bench in about a half hour from starting.

Spray Painting

Try to arrange things so you can do the entire job without moving the work. If you're painting a box or other many-sided surface, think about how you will move it when it's wet. You'll soon accumulate a few wood

Take this with you when you go looking for lettering supplies. Here are a pen holder, a Leroy adapter, one of the Leroy lettering tips, and a very convenient ink dispenser.

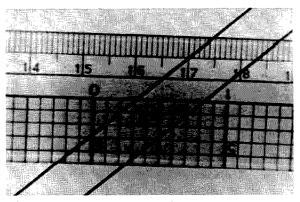

blocks and other objects for propping things in place. A panel or chassis will rest nicely on top of a piece of pipe and can easily be rotated to get at all sides.

The Rustoleum enamels I've been using are well behaved, and flow very nicely a few seconds after going onto the metal. The object is to get just enough everywhere to cover the work. Avoid overdoing by putting on a coat that's visibly too thin. Estimate your progress and then put on a little more. Corners seem to need special attention.

Those handy spray cans will generate an awful mess. I don't think spraying outdoors is practical, so here is a way to keep the stuff under control. Find a cardboard box fifteen inches or more deep and large enough so your work doesn't seem cramped in it. Put in three or four layers of cheese-cloth a few inches from the closed back. Scotch tape will do the job and a few safety pins may help. With some newspapers over the adjacent bench, you will have a spray booth that works much better than you'd believe without trying it. The cheesecloth reduces the disturbance of spraying and catches most of the waste spray.

The Rustoleum people suggest spraying from a distance of a foot or so. Start the spray off target, and then swing it across the work. Keep it moving! Spray, check, and spray again. With practice you can learn to paint a vertical surface with little or no bead developing along the bottom edge.

You'll find a little note on the spray

Closeup of a convenient scale for drawing guidelines. Two parallel guidelines included.

can about cleaning the nozzle when you're done spraying. I have a three-year old can of spray which works fine. Another didn't get cleaned properly some time, and it doesn't work so well. Be sure to clean the nozzle as per instructions!

When you're done spraying, get right away from the work. Come back next day. Some heat will help things along if you're in a hurry. But this will increase the chance of dust, dirt or damage. I have done the complete job in one day, but a slower approach will give nicer results.

When the work has dried sufficiently, almost anything that will apply ink to paper will serve for labeling. I generally use a Leroy pen set. Bookstores, paper supply houses, and many other businesses carry drafting supplies which may be usable. Try Speedball products. Lettering jigs and guides that work well on drawing boards are less successful on real panels with their holes, screw heads and other obstacles.

Why not learn draftsman's lettering? Good books on drafting devote a chapter or two to the subject, or little, soft-cover pamphlets come complete with neatly marked practice pages. One of these is well worth 50c or so. Practice a little bit every day . . . you will find yourself using your neat new lettering on schematics, notes, and other applications as well as shiny fresh panels.

Rough out your panel before you mark it up. Almost every time I omit this simple step I regret it. Just make up a freehand sketch about full size and write the lettering on it in pencil. Revise until it looks right to you. Don't get fouled up in rules of proportion and all that.

Then you're ready to put lettering guidelines on the panel. A dull-pointed tool, which will scratch but not penetrate the soft enamel is required. If not overdone, these lines will disappear when you apply the clear finish coat. A nail will take a good point, use it gently! A transparent five-and-dime ruler with parallel guidelines on it serves to get your parallel lines in place. The lines should be just strong enough to be visible through the ruler. Wash the ruler just before using, and keep fingers and hands off the panel. A handy sheet of paper enables you to rest your hand where convenient.

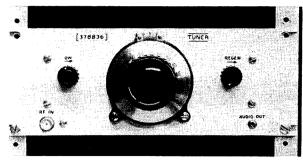

I use a Leroy pen for lettering. You'll probably want to start with a #1 and a #3 point, and pick up a #0 and a #2 later. These odd-looking devices are very good once you get used to the loose piece in the center. This serves to keep the tip from drying rapidly, as it does in a conventional pen. If the tip does seem dry, jiggle and rotate the center piece til the ink flows freely. The flattish working ends are relatively immune to digging into the work.

Choose the larger point for larger lettering to avoid a spidery appearance. Mount the pen in the holder and go at the panel, just as in practice with a pencil. If you can't make out the guidelines, change the lighting a little bit. They should be just visible as white against darker, rather than the usual dark against light seen on paper.

If you make a booboo, and we all do, a handy Kleenex dampened with a little spit will rub out the mistake. Then blow some humid breath on the panel, and wipe off the fogged region with a piece of dry Kleenex. Do this one or twice more. This gets the last traces of spit off, so the new lettering is the same weight as the uncorrected lettering nearby. If you don't do this, it will be heavier.

A grease contamination far too thin to see will spoil the fresh enamel's excellent wetting properties. Have a few pieces of clean paper handy and keep most of the panel covered while lettering. You may get so involved with neat lettering your hand wanders off the protective paper. Sorry about that!

When the lettering is finished, set the panel aside to dry for a few minutes to a half hour before going on to the clear enamel finish coat.

This panel was completely finished in one day. Slight crinkling of the finish at one point probably does not show in magazine copy of photo.

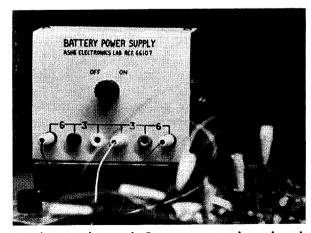

Finishing up

I once applied lettering and finish coat eight hours after enameling, with the help of heat for quick drying. But I recommend a drying period of at least 24 hours in a warm place. Try your luck on some scrap. If the color coat is insufficiently cured, it will wrinkle free of the metal when the finish coat goes on.

After the finish coat has hardened for at least 24 hours, you're ready to go ahead with final assembly of the project. Be nice to the fresh, soft enamel! If you wash your hands and wipe tools with a paper towel just before starting work, the whole project will stay quite surprisingly clean.

As a nice final touch, if you want to wait at least another 24 hours, the enamel will take a coat of auto body wax. Car painters like to have you wait a month or more, and I think they use materials similar to mine. Well, this wax finishing really puts the grand touch on. You'll be very pleasantly surprised at your results, and it really is worth the time it takes!

. . . W2DXH

Another simple panel. Oops, seems to be a breadboard in there.

An Automatic Keyer Using Intergrated Circuits

Here's a very simple integrated circuit keyer that uses very few parts.

This article describes one of many possible applications of integrated circuits to amateur radio. The keyer described is self completing, completely adjustable from less than one word per minute to sixty words per minute, and could be built in a pocket match-box. The complete keyer can be built for less than thirty dollars (\$30.00).

Operation

A clock generator consisting of a unijunction transistor and an R-C combination is used to determine the speed of operation. The basic relation of a space equals a dot, and a dash equals three dots was used and is constant regardless of the speed. The clock pulse is connected to the dot flip flop through the logic built into the flip flop package. The output of the dot flip flop drives the dash flip flop. The output of both flip flops are connected to a gate which has an output if either of the inputs go to zero.

The output of the gate in this keyer is used to drive a transistor to control a relay. It is possible to use a transistor only and build in weighting circuits to give individual desired effects; but, the emphasis of this article is on the application of the integrated circuit.

Texas Instruments integrated circuits were available at reasonable prices and were chosen for this application. The SN7302 package (.125 X .250 X .035 inch) contains two flip flops and all of the necessary logic circuits required for proper gating. (38 transistors total) The SN7360 quadruple two input NAND/NOR gate contains 24 transistors total in the same size package. Only one of the four gates in this

package is used.

The integrated circuits operate on 3 to 4 volts dc. The minimum voltage which will operate a unijunction transistor properly is 9 Vdc, therefore, a 5.6-volt zener diode is used to drop from 9 Vdc to 3.4 Vdc. The zener diode was chosen over a divider in order to maintain a low power supply impedance for the integrated circuits.

Circuit description

Refer to the schematic diagram. Fig. 1, and the logic chart, Fig. 2. The capacitor C3 charges up at a rate determined by the speed control R1 and R3. When the voltage across C3 reaches the intrinsic stand-off ratio of Q1 (firing point) C3 is discharged through R4. This provides a positive pulse several milliseconds long with an exponential decay. The flip flops trigger only on the trailing edge of the clock pulse so this signal is passed through C5 and R5 to provide a fast rise and fall pulse.

The terminals marked on the schematic with an asterisk are the dot flip flop. The flip flop operation is as follows: Q. HAS A 2.5 V. output and \overline{Q}_{\bullet} (pronounced not Q) is at zero. If K. is positive when a clock pulse is applied to CP. the flip flop switches and Q. and \overline{Q}_{\bullet} switch modes. Since J. is connected to +3 volts the following clock pulse reset the flip flop to its original mode. This action represents a dot and space. If the dot key is held down the next clock pulse simply triggers the flip flop again and if the key is released the next pulse resets the flop flop to a space condition and it remains.

The terminals of the SN7302 without an asterisk are used for the dash flip flop.

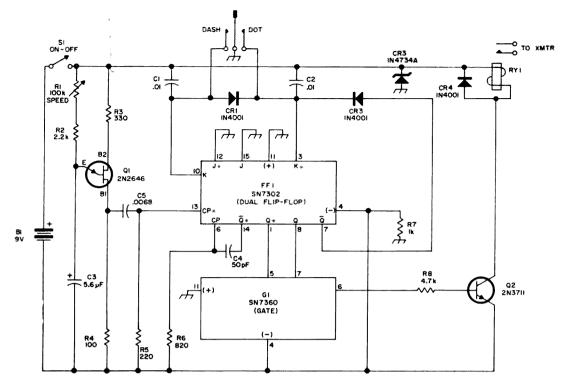

Fig. 1. Schematic of W5FQA's integrated circuit keyer.

The dash operation is as follows: The key is moved to the dash position and a positive voltage is applied to K. through CR1 starting a dot sequence. Q. goes positive at the start of the dot. This positive signal is differentiated by C4 and R6 providing a fast rise and fall pulse at CP. (The clock pulse input for the dash flip flop.) The input at CP triggers the dash flip flop causing O to go positive since K is positive. The next clock pulse triggers the dot flip flop, but it will not trigger the dash flip flop until Q. goes positive again which is the following pulse. Then the dash flip flop changes state, but the output of the dot flip flop is still present and will remain for the length of a dot which gives a dash length of 3 dots. If the key is released before a dash is complete a positive voltage is still applied to K. through CR3 which makes the dash self completing.

The operation of the gate SN7360 is as follows: If either and/or both inputs are zero the gate has an output. If both inputs are positive the output is zero.

Information about the integrated circuits used in the keyer is available from Texas Instruments, P.O. Box 5012, Dallas 22, Texas. Request bulletin No. DL-S 657650, July 1965.

Construction

The authors keyer is constructed on a Vero printed board, however, for one who does not have an integrated circuit soldering iron the TI Mech-Pac connectors are ideal. Wiring is not critical and phono wire or #30 to #32 hookup wire is recommended.

The positive 3 volts for the integrated circuits is grounded to prevent floating the common of the key. CI and C2 shunt any rf to ground. Shielded lead should be used to minimize rf pickup. The battery drain is 30 mA key up and 50 mA key down. A 9 and power obtained from transmitter or receiver B+.

volt zener may be substituted for the battery

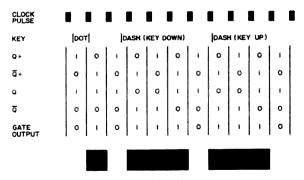

Fig. 2. Logic diagram of the keyer.

Edison—The Fabulous Drone

Was Edison really the great genius schoolbooks tell us he was? Or was he simply very diligent and hardworking?

The Great Man confided that he tried 'everything' while working on inventions. When 10,000 experiments with a storage battery went down to failure, he said: "I have not failed. I have just found 10,000 ways that won't work."

He argued with Nikola Tesla, the brilliant Serbian engineer and scientist, telling him that AC electricity was a "waste of effort and money".

"Looks like a bunch of Chinese laundry markings," he remarked of his hired mathematicians' worksheets.

He said: "Genius is one per cent inspiration and 99 per cent perspiration."

Most people think Thomas Alva Edison was perhaps the world's greatest inventor. But in comparison to his contemporaries, he was an inveterate fiddler, who scorned abstract work to tinker about with one failure after another.

Tesla observed Edison work methods thus: "If Edison had a needle to find in a hay-stack, he would proceed at once with the diligence of the bee to examine straw after straw until he found the object of his search." Tesla said further: "I was a sorry witness of such doings, knowing that a little theory and calculation would have saved him ninety per cent of his labour."

Edison plodded along, content to improve on existing ideas, insistent on hand work over brain work, and often completely blind to the uses of his own great and original work. Of his first phonograph, he said: "Maybe we could use it for some sort of telephone repeater."

In later years he said of its first successful test: "I was never so taken aback in all my life. Everybody was astonished. I was always afraid of things that worked the first time."

Even after patent rights were issued to manufacturers, Edison claimed it was "just a fad, and would be completely forgotten in five years". As late as 1925 he would not concede that electronic phonographs were superior and maintained that T. A. Edison, Inc. would make an improved mechanical phonograph for long playing records. Also in 1925 he noted that the 'radio

Also in 1925 he noted that the 'radio craze' would soon pass. "The present radio . . . is certainly a lemon. It will in time cure the dealer of any desire to handle any kind of radio." He also insisted that the public would not stand still for having to listen to the programming the broadcasters provided.

In 1926, though very hard of hearing, Edison tested an electronic phonograph perfected by Bertil Hauffman, a Swedish engineer, at the Edison Laboratory. Edison found the reproduction 'distorted and terrible' and ordered that Hauffman be fired. Son Theodore, director of the works, arranged for Hauffman to work hence in a part of the laboratory that Edison was not likely to visit.

Edison once said that he enjoyed his deaf-

ness because it permitted him to concentrate. Though his progressive deafness made him almost stone deaf in elder years, one wonders if the affliction also allowed him to ignore criticism in earlier times.

Another facet of the Edison myth is the famous story of his sleeping only four hours a night. John J. O'Neill reports in his biography of Tesla: "It was a regular practice with Edison to sit down in his laboratory and doze off into a three-hour nap about twice a day."

Edison was strangely adverse to theoretical work himself; as a thinker, he was second rate—as an administrator, second to none. The 'Wizard of Menlo Park' hired batteries of mathematicians and physicists, laughed at their theoretical approach, but utilised their results.

When the young genius Nikola Tesla came to this country, he had a letter of introduction to Thomas Edison, four cents in his pockets, and the key to alternating current electricity—today's housepower—locked in his mind. Edison offered him a meagre eighteen dollars a week, providing he never spoke of AC.

Tesla proved himself an able engineer and inventor, regularly submitting improvements for Edison equipment. When Tesla suggested research toward improved dynamo manufacture, Edison told him: "There's fifty thousand dollars for you in it—if it works." Inside the week, Tesla presented the design. When he finally had to ask about the money, Edison grinned and said: "I guess you just don't understand our Yankee humor."

Tesla quit. Some months later, he had interested investors in his ideas for AC, constructed working models, and applied for a patent. The U.S. Patent Office responded that the ideas contained in the original patent application were so far-reaching that no less than forty would cover them!

George Westinghouse, industrialist and inventor himself, offered Tesla one million dollars for the rights and the Westinghouse Electric Company was formed. This was prologue to the biggest battle of the 19th century: a technological war in which Thomas Alva Edison was the prime antagonist.

Edison had recently spent \$2 million with his DC system in New York City. The financial threat posed by Westinghouse and Tesla could not be ignored. Although Edison had said AC was "a waste of effort and money", he found his system impractical to produce voltages higher than 220, as the dynamo commutators heated badly. Too, line losses necessitated either large, expensive conductors or power stations spaced every mile or so.

DC power left the generating plant at about 120 volts; the users closest to the plant had the brightest lights, sometimes so much so that bulbs burned out frequently. Perversely, those at the end of the line had light hardly better than candlepower, because of the voltage drop along the line. With Tesla's AC system, alternating current could be transmitted equally to home or factory, with negligible power loss in the lines.

Edison wrote: "Just as certain as death Westinghouse will kill a customer within six months after he puts in a system of any size . . . it will never be free from danger."

Westinghouse argued that of thirty deaths by electricity in 'recent' years, sixteen were from 'safe' DC circuits, and none from Westinghouse equipment. During one period Edison lost about a workman a month with safe direct current and almost burned down the fashionable Vanderbilt home on Fifth Ave. A fire started when metallic-threaded draperies shorted out the wiring which had been placed behind it. Mrs. Vanderbilt returned home to find a confusion of firemen, assistants and Edison himself. Learning that there was a generating plant in her cellar, she became 'hysterical' and declared she could not live over a boiler. "We had to take the whole thing out," Edison ruefully remarked.

To sway public opinion in the "battle of the currents", Edison and Charles Batchellor -ironically the man who gave Tesla the letter of introduction to Edison-demonstrated the horrible dangers of alternating currents by electrocuting cats and dogs, using a one kilovolt generator. They paid eager schoolboys twenty-five cents a head for all the animals they could deliver. It is said that the house pet population around West Orange stood in danger of being annihilated. During one of these edifying illustrations for guests, Batchellor lost his hold on the dog he was about to electrify and himself received the shock. As he put it later: "The sensation was of an immense rough file thrust through the quivering fibers of the body."

After this, Edison published an article saying in part: "I have not failed to seek practical demonstration . . . I have taken life—not human life—in the belief that the end justifies the means." Yet in the final battle of this strange war, Edison seemingly reversed his opinions and requested permission to install AC equipment in upstate New York. Westinghouse hastily agreed.

It might be said that the news of the installation came as a shock to Westinghouse—it was the first electric chair. The New York State Legislature had adopted a statute in 1888 to provide for capital punishment by electrocution. H. P. Brown, a former research expert for Edison, supervised the installation of the 'hot squat' for the Edison General Electric Company.

On August 6, 1890, convicted murderer William Kemmler was to be executed. The first attempt at death by legal electrocution was a failure, as the electric force was too weak. The unfortunate man was led away. After quick modification to the chair, "the miserable work was perforce done again, resulting in a spectacle much worse than hanging."

A frantic Westinghouse recouped by obtaining the contract to provide power for the Columbian Exposition of 1893. Tesla had his own exhibit there, where he mystified fairgoers with his scientific marvels. The climax of the many performances was the passing of one million volts of AC through his body to melt a copper plate. It was not high voltage that killed, he maintained, but the destructive heating effect of high currents. High amperage DC could and did kill as readily as AC. While working up his demonstrations, he discovered the medical principle of diathermy.

The public was won over to AC and in 1895, Tesla harnessed Niagara Falls. His powerhouse was completed, providing AC for Buffalo, twenty-two miles away. It was hailed as the greatest engineering achievement in the world to that date.

In 1896, a mysterious cigar-shaped air-ship was seen by hundreds of people over San Francisco Bay, and subsequently was reported in successive eastward sightings. A New York *Herald* reporter obtained this statement from Edison, who disclaimed any knowledge of the never-identified craft: "I perfer to devote my time to objects of commercial value. At best airships would only

be toys." A few years later, he was congratulating Alberto Santos-Dumont for inventing powered flight, not recognising the achievement of the Wright brothers.

The Edison Effect—the expulsion of particles from a heated filament—grew from experiments with the light bulb. Edison found that bulb life was shortened by the deposit of carbon from the filament. He sketched in his notebook the first two-element vacuum tube as a solution to the problem, having found that current would flow into the second element. This forerunner of today's diode was patented but never used, and the patent lapsed.

With the diode, his discovery of the 'etheric force' and a subsequent patent of wireless transmission based on electrostatic induction, he had in his grasp the elements of a complete radio system several years before Hertz demontrated the existence of radio waves. Later in life, he said that it was a pity he had not seen any connection between them.

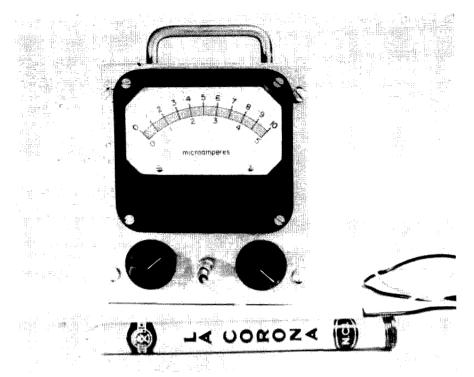

His first major invention, the carbon but ton microphone, is virtually the same today; it was a symbol of much of his work, since it improved an existing idea, the Bell device. Edison came, as it were, into a technological vacuum, purifying existing and imperfect concepts, and applying much of the random electrical science accumulated over fifty years. He did enough that he could well say in later years his productivity brought him "awards by the quart". He patented over 1,100 inventions and gained a vast reputation while his more brilliant and less understood contemporaries are all but forgotten.

George Westinghouse himself patented over 400 inventions in his lifetime and founded 60 companies.

Charles Proteus Steinmetz, whom Edison liked "because he never spoke of mathematics to me", published the law of hysteresis when he was only 27, went on to produce artificial lightning and delve into higher mysteries. He is little known today.

Nikola Tesla, besides giving the world AC, demonstrated radio control before the turn of the century, developed a working system of broadcast power, lighted his laboratories with wireless fluorescent lights in 1889, and had over 700 patents to his credit when he died in 1943. Yet he is the forgotten man of electrical science.

Edison, the Great Man, reigns supreme. . . . Elkhorne

A Sensitive RF Voltmeter

One of the handiest test instruments around the ham shack is the rf probe or rf voltmeter. This almost indispensible unit may be used for neutralizing transmitters, tuning up oscillators and in many other general tasks around the shop. Most hams simply purchase an rf probe to go along with their VTVM, but these probes are usually limited to an upper frequency range of somewhere around 250 MHz. Another serious limitation of the familiar VTVM rf probe is that the lowest voltage range on the VTVM is typically 1.5 volts. Some of the latest models have voltage ranges down to 0.5 volts tull scale, but the vast majority are not that

sensitive. When working with transistor rf stages, the millivolts (thousandths of a volt) become very important, and a more sensitive rf voltmeter than the common household VTVM must be used.

There are several approaches to this problem, but most of them are not very simple. The commercial instruments that read one millivolt full scale or less are quite complicated; they rectify the rf, chop it up at 1000 Hz, feed it into a very high gain, narrow passband ac amplifier, rectify it at the higher level and drive a meter movement. This is a very effect approach, but instruments using it cost upwards of \$500. The rf

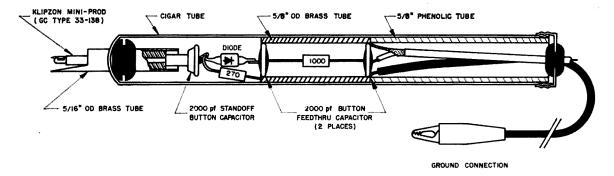

Fig. 1. Cutaway view of the sensitive rf probe. Note that the cigar tube construction results in an essentially coaxial structure; this type of construction ensures relatively flat response up to 500 MHz.

voltmeter I will describe here is not nearly sensitive enough to read 1 millivolt full scale, but with care in construction, you can readily detect 30 or 40 millivolt signals at 500 MHz. This is about 15 times more sensitive than the most sensitive VTVM and about 50 times more sensitive than the average one. Higher sensitivities are obtainable, but noise becomes the limiting factor with the simple construction described here.

With this rf probe, response is relatively flat from about 50 MHz all the way up to 500 MHz. The secret to this unit's wide frequency range lies almost exclusively with its layout and construction. First of all, the probe itself is essentially coaxial in nature, with the filter components mounted in a brass tube. To maintain leakage at an absolute minimum and to minimize series inductance, button mica capacitors are used in conjunction with a coaxial input. The result is a probe that will quite accurately measure small levels of rf voltage up to about 500 MHz. Above 500 MHz you can still get meter deflections with small rf voltages, but the response gradually falls off. This frequency roll off is a result of the parasitic and leakage elements that start to take effect at these higher frequencies. Above 500 MHz for example, it is difficult to predict the dielectric characteristics of molded carbon resistors. In some cases there is sufficient leakage between the two leads of the resistor to completely nullify the resistance.

In addition to the compact and coaxial nature of this probe, the low value of load resistance, 270 ohms, tends to maintain an input-output characteristic which is almost completely independent of frequency from several MHz up to 500 MHz. With the component values shown in the schematic, the

response gradually falls off below 50 MHz; at the expense of flat UHF response, the capacitors may be increased for response in the 3 to 30 MHz region. For the high frequency range the input coupling capacitor should have a value of about 500 pF and the filter capacitors should be 2000 pF. For lower frequency use of course, it is not necessary to maintain the coaxial structure of the probe nor to use the more costly button capacitors.

The selection of a diode depends on the frequency range desired. Up to about 100 MHz, almost any germanium diode will work quite well; the 1N34A is an excellent choice for this range. For higher frequencies however, many diodes are constructed in such as way that they exhibit high values of series inductance and leakage capacitance. For this reason, the familiar 1N21 and 1N23 microwave mixer diodes represent excellent choices for a voltmeter of this type which is designed for VIIF use. The 1N82A is another diode that works quite well up to 1000 MHz or so. Each of these diodes exhibits different characteristics and even diodes of the same type are not exactly identical.

It is a pretty well known fact that all semiconductor diodes exhibit a square law

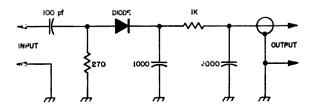

Fig. 2. The sensitive rf probe. For UHF use the expacitors should all be button types to minimize series inductance; for the lower frequencies, conventional types will suffice.

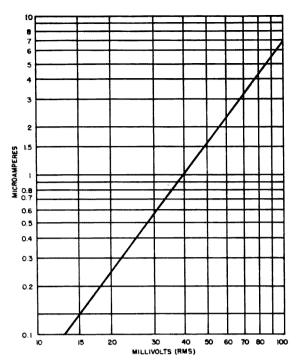

Fig. 3. The microampere per volt characteristic of a IN34A diode in the square law region. Above 100 millivolts or so, this curve becomes linear.

input-output characteristic up to several hundred millivolts. With germanium diodes the square law region is from zero to about 100 or 200 millivolts; silicon diodes are slightly higher, to 600 or 700 millivolts. The 1N34A diode for example exhibits a sensitivity of 700 to 1200 microamperes per volt squared in this region; a typical 1N34A μ A/V curve is plotted in Fig. 3. It should be pointed out that this curve varies with temperature, the amount again depending upon the individual diode used. However, in amateur applications this is usually not a problem because the probe will normally be used at room temperature. Above the square law region the sensitivity of semiconductor diodes is essentially linear and typically on the order of 5 milliamperes per volt.

Because of the large variance between diodes, the rf probe must be calibrated against a known source for maximum accuracy. Because of the construction of this probe, the calibration sounds much more complicated that it actually is. Since the probe is essentially flat up to 500 MHz, it may be calibrated at 100 MHz or so; most VTVM's are accurate enough at this frequency for calibration purposes. All you have to do is set the output of your signal

generator for 1 volt on the VTVM. For best results your generator should be operating on a fundamental and relatively free of harmonics. Since 1 volt is within the linear range of the diode in the VTVM rf probe, it should be reasonably accurate. Now all you have to do is connect an attenuator between the one volt source. You can breadboard an attenuator circuit for this purpose, or use a switchable attenuator such as that described by WB6AIG and WA6RDZ1. When the input-output characteristics are plotted on graph paper, you should end up with something like the curve of Fig. 3.

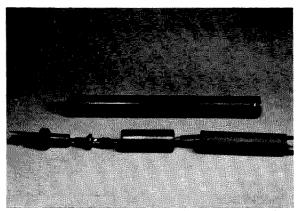

Construction of the probe is quite simple and is based upon the use of an aluminum cigar tube, the kind those 50c cigars come in. If you can't get one of these or don't smoke, an old pen light or piece of aluminum tubing will work with a little modification. The tip of the probe is made up from a Klipzon Mini-prod (General Cement 33-138) and a piece of 16 inch brass tubing from the hobby shop. This tubing is popular with slot car enthusiasts, so it shouldn't pose any procurement problems. One end of the mini-prod has a sharp tip with a small clip that may be clipped unto wires; the other end accepts a pin plug.

Apply a little epoxy cement to the miniprod and push it into the brass tubing. The mini-prod fits snugly in the tuning and is held firmly in place by the cement. Now place a 1/16 rubber gromment around the tube and push it about half way down;

cement it in place with epoxy.

While the epoxy is setting, take a 100 pF standoff button mica capacitor and solder it to a pin jack; this will eventually fit into the end of the mini-prod when the probe is complete. Cut a piece of % inch brass tubing about an inch and a half long and solder two button capacitors and a 1000 ohm resistor inside as shown in Fig. 1. This "filter" assembly should slide easily into the cigar tube. Also drill a 1/16 inch hole in the end of the cigar tube for the mini-prod assembly.

Install the diode and a 270 ohm resistor as shown in Fig. 1, using the very shortest leads possible. The cathode of the diode goes to the center pin on C2; the 270 ohm resistor is soldered to the brass tube. On the other end of the tube connect a length of cable; this lead will be connected to the microammeter. Install the complete assembly (miniprod, CI, CRI, RI and the filter) into the

Disassembled rf probe. The Klipzon Mini-prod is on the left, the button coupling capacitor, diode and 270 ohm resistor to the right, followed by the filter and phenolic tube. The cigar tube housing is in the background.

cigar tube and cut a length of % inch phenolic tubing so that it protrudes about ¼ inch from the end of the cigar tube. When the cover is in place this tube will compress the unit together and ensure a physically strong assembly. The shielded lead is brought out through a small rubber grommet mounted in the cover.

In addition to the rf probe, you will need a very sensitive microammeter for measuring small levels of rf. Occasionally 10 or 20 microampere movements are available at bargain basement prices, but usually another approach is necessary; the sensitive microammeter illustrated in Fig. 4 is a good example. This meter uses a high gain transistor meter amplifier to obtain full scale

readings down to 10 microamperes full scale on a 1 milliampere meter. With a full scale calibration of 10 microamps, it is quite easy to read a half microamp or so; this corresponds to 28 millivolts peak to peak with my probe.

The sensitive microammeter illustrated schematically in Fig. 4 consists of a current amplifier with the 1 mA meter in a bridge circuit². This circuit is quite stable with temperature and slight variations in supply voltage may be compensated by the zero control on the front panel. Almost any high gain transistor will work in this circuit, but silicon is preferred because of its better leakage characteristics. The only other requirement is that the transistor must maintain linear current gain and high beta at low collector current levels; the 2N3392 is inexpensive and works very well.

With the switch in the 10 microampere position, the 10k gain control is adjusted to provide 10 microamperes full scale. With a 1 milliampere movement, this corresponds to a current gain of 100. For full scale readings of 50 to 200 microamperes, meter shunts are proved for 5 and 20 mA full scale with the 1 mA movement; the transistor amplifier will maintain a current gain of 100. For meter readings of 1 milliampere, the transistor amplifier is disabled and the meter is operated in the normal manner. The value of the shunts may be calculated by using the formula found in any of the hand-books.

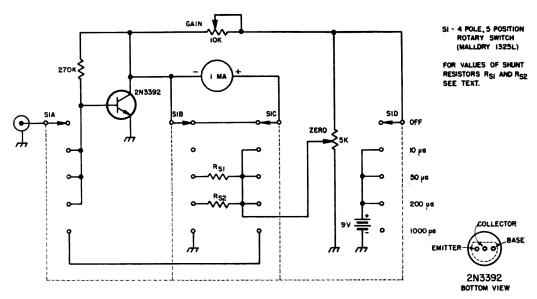

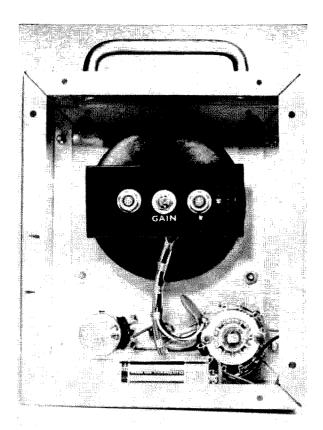

Fig. 4. Transistorized microammeter. This instrument will provide full scale readings down to 10 μ A. Although a 2N3392 was used here, any high gain silicon transistor that maintains high current gain at low collector current levels is suitable.

In my transistorized microammeter I mounted the transistor amplifier circuitry and meter shunts on a phenolic strip connected to the meter terminals. The gain potentiometer is also mounted on this strip. With a circuit as sensitive as this, noise can be a very serious problem if the circuit is not properly shielded. In this case a small coaxial cable was used in the input and the amplifier and meter were built into a metal box. In addition, the input was bypassed with a 0.01 µF disc capacitor.

With the sensitive microammeter and calibrated probe, it is quite easy to accurately measure rf voltage down to 30 or 40 millivolts. However, since this is a peak responding instrument, you have to be a little careful or you will obtain some very optimistic readings. If there is any harmonic content in the waveform you are reading, it is apt to be quite a bit higher than predicted, and the rms value will not be 0.707 of the peak reading; the 0.707 value applies only when the waveform is sinusoidal. This is not usually the case with rf oscillators and amplifiers, but if the harmonics are suppressed with high Q tuned circuits, the error will be negligible.

In addition to measuring actual rf voltages, this probe has several other uses. It may be used as a very sensitive untuned field strength meter by simply clipping a short length of wire to the tip; in some cases where the rf field is strong and the probe can be placed close enough to the transmitter, this may not be necessary. Hence another precaution: don't use the probe in strong rf fields when measuring small rf voltages; the rf field vill negate the voltage reading. This probe may also be used as a demodulator for a VHF sweep generator. Just connect the probe to the circuit being swept and connect the output to your oscilloscope. It may also be used to measure the SWR along a piece of open wire transmission line (or twin lead). When the probe is brought in close proximity to the transmission line, it will provide an upscale reading on the microammeter. The ratio between peaks and valleys as the probe is moved along the line is the voltage standing wave ratio.

In some measurements you may find that the probe will load down low-capacitance high-Q circuits. If you are only interested in peaking the circuit, and many times this is the case, this effect may be minimized

Inside of the meter amplifier. The transistor and gain calibration control are mounted on a piece of bakelite attached to the meter terminals. The rf probe disassembled. See Fig. 1.

by connecting a resistor in series with the probe. The Klipzon Mini-prod is ideal for this purpose because it will securely hold one lead of the resistor; the other lead may be used for probing. If a 5000 ohm resistor is used, it represents less than one pF coupling above 30 MHz; this should eliminate any detuning effect of the probe.

There are many other uses for the sensitive rf probe, limited primarily by the ingenuity of the user. But in it main application, that of measuring very small rf voltages, it is unbeatable for its expense and complexity. Although high rf voltages or mechanical shock may cause permanent damage to the diode, my probe has proven to be particularly resistant to burnout and has accepted peak surges of 500 Vdc and 120 Vac with no apparent effect on calibration. . . . SDRAWKCAB Power Supply

Articles have already been written about building kW supplies with TV power transformers, using voltage doubling and series capacitors. The solid state man, shunning the lethal voltage approach to rf power generation, looks for a way to lower the line voltage. With this in mind, and with a junked TV in the shack, the supply shown here evolved. With 115 V in, the outputs are as follows:

Unregulated 16, 21, 32, 41 Volts Regulated 12, 24 Volts

The transformer is hooked up with the secondary connected to the line, and the primary as the input to a bridge and filter. Four levels of voltage are available at the unregulated output, which is the next best thing to owning a Variac. With a little more switchcraft, and with more filament windings, more levels can be had. The HV winding center tap provides a choice of high or low outputs, while the filament windings give series aiding or opposing differential adjustment at either level. Stud silicon diodes are used in the bridge. The .008 F capacitor is probably a little fat for the application, and a mere 4,000 µF would still guarantee a T9 report on the air.

The regulated outputs are at the 12 and 24 volt levels for this supply, but depending on your transformer, or your oscillator requirements, these could be modified to 9 and 18 volts, or even lower. For the loads presented by solid state receivers, the stud

Here's KIUBA's transistor power supply.

zener is an adequate regulator, so no series type regulation had been built in. On transmit, a voltage "droop" of over 25% has gone unnoticed on the air, as has a ripple considerably higher than the 0.1 V of this supply. Accordingly, no attempt has been made to regulate anything but the oscillator supply. If too much current is drawn from the unregulated output, however, regulation cannot be maintained.

Important criteria for selecting the transformer are:

- 1. The turns ratio
- 2. The internal resistance of the wind-
- 3. The number of filament windings. Transformers which give the highest voltage when normally connected are not necessarily what you want for this supply, since they may give too low an output when connected backwards. Also, their HV windings may exhibit high resistance which reduces the stiffness of the dc output. The author's supply has an internal resistance of 8 ohms. which limits maximum output to 53 watts. More filament windings mean greater range of differential adjustment.

The aluminum chassis acts as a heat sink for the bridge and zener diodes. All diodes are isolated from chassis ground with mica washers to allow a choice of positive or negative grounding. Threaded 6-32 stock holds down the capacitor, but it could have been epoxied to the chassis. The AC line switch is DPDT with center off position to minimize the number of controls, and it also cuts in the second zener when in the "HIGH" position. The pilot light is visibly dimmer in the "LOW" position, but it can still be seen. Grommets protect the transformer leads and the capacitor lugs.

On low voltage, a direct short will not blow the % Amp fuse, but component dissipations are within safe limits. The transformer is not operated anywhere near its allowable power limit for step-up operation, but it exhibits less than 10°C rise at full load, and should be adequate until the advent of the solid state kW.

. . . KIUBA

A Panadapter Converter

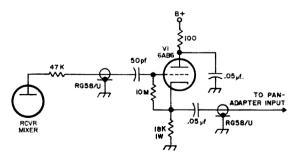

Having trouble getting those pretty pictures with your panadapter? Maybe you need an isolating amplifier.

I recently got a panadapter It worked fine with a signal generator, but gave pretty dismal results when I connected it to my receiver.

A careful search through the literature turned up all sorts of interesting notions on how to connect a panadapter to a receiver. Each was tried without success. Some loaded the mixer too much. Others attenuated the signal too much. Finally a reasonable presentation came on the screen, but only after reducing the length of RG-58/U connecting the adapter to the receiver to a ridiculous length that left the panadapter back to back with the receiver.

Something had to be done. A cathode follower was the obvious approach. One was installed as close as possible to the mixer stage. This gave a very high impedance to the mixer stage, but a low impedance into the coax running to the panadapter input. The results were excellent.

Since most receivers have an accessory socket on the back, this seemed to be an ideal way to get the B+ and filament voltage, and at the same time provide a mounting for the cathode follower circuit. The

A simple panadapter converter.

origonal unit was constructed in a Mini-box 15% x 21% x 234, using the piece that has the two ends on it for the chassis.

An octal plug is mounted on the long side. This not only makes the necessary electrical connections but also holds the assembly in place on the back of the receiver. The cathode follower circuit is assembled on one end, and an octal socket is mounted in the other end in case any additional accessory is to be connected to the receiver.

A 6AB4 tube was used because it was handy, but any of a number of other tubes might be substituted with only minor changes in the circuit. A more compact unit could probably be built easily by using a triode Nuvistor. Construction is straight-forward but lead lengths should be kept to a minimum, and the length of RG58/U between the mixer and the cathode follower should be kept as short as possible to minimize attenuation. The 47 k resistor should be as close to the plate connection as possible, and likewise the 50 pF capacitor as close to the 6AB4 grid as possible. The 100 ohm resistor in the plate circuit of the 6AB4 provides decoupling and was adequate in this installation, but a different value might be required in other installations.

Using this unit between the receiver and the panadapter, no detuning of the mixer is noted when connecting to it, and enough coax to allow the panadapter to be removed to a respectable distance from the receiver has little effect on the input signal. In fact despite the fact that the gain of a cathode follower is of necessity less than 1., the lowered impedance gives the effect of an actual gain.

73 Useful Transistor Circuits

Useful transistor circuits for audio and speech equipment, receivers, transmitters and test equipment.

Circuits for Audio Equipment

Direct coupled amplifiers

The direct coupled amplifier illustrated in Fig. 1 is just about as simple as possible, but provides very usable results. The collectors of the first two transistors operate at about 0.3 volts; this type of operation vields somewhat less than normal gain, but provides considerable reduction in noise produced at the input by the transistor. The biasing of the first stage is controlled by resistor R1 and because of the direct coupling between stages, indirectly controls the bias to the other two stages. Since the gain and leakage varies widely between different transistors, this resistor must be adjusted experimentally to provide optimum bias for the last transistor (Q3). This is easily done by adjusting its value until there is 0.8 volts across the headphones (points A and B in the schematic).

MIC VOLUME QI Q2 Q3 A PHONES (IKA DC) B

Fig. 1. Simple direct coupled amplifier. Transistors Q1, Q2 and Q3 should be the 2N207, 2N584, 2N1098, SK3003, GE-2 or HEP-254.

Since R1 is connected to the collector of Q3, bias variations caused by changes in temperature are reduced by negative dc feedback introduced by this resistor. For example, as the leakage in Q1 increases with temperature, the collector voltage on Q3 decreases. The increased leakage is partially compensated for because the lower voltage on Q3 causes less current to flow through R1. Generally speaking, this circuit will compensate quite nicely against temperature changes up to about 100°F. Above 100° it is possible that the transistor will be driven into nonlinear operation with resultant distortion and reduced power output.

The dc resistance of the headphones is very important in this circuit because the

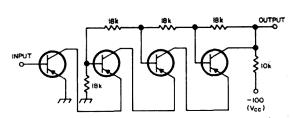

Fig. 2. High voltage direct coupled amplifier. The gain of this amplifier is equivalent to both sections of a I2AU7. All transistors are 2N384, SK3008, GE-9 or HEP-51.

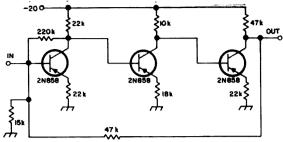

Fig. 3. This simple direct coupled amplifier provides 30 dB gain and identical 1500 ohm input and output impedances. For higher gain, similar units may be cascaded up until 10 volts peak to peak is obtained at the output.

voltage drop across them determines the operating conditions of all three stages. For optimum operation, the dc resistance of the earphones should be in the neighborhood of 1000 ohms. Most phones with an impedance of 2000 ohms have a dc resistance of 1000 ohms, but if you're in doubt, the resistance may be easily measured with an ohmmeter.

The main advantage of the high voltage direct coupled amplifier in Fig. 2 is that it may be connected directly to a rather high value of B+. Its gain is equivalent to a single 12AU7 (both sections) and because of the direct coupling, provides extremely wide bandwidth. Although the input impedance of this circuit is only 2000 ohms, it is still very useful for many applications where a simple amplifier is required.

Another very simple direct coupled amplifier is illustrated in Fig. 3. This amplifier provides almost exactly 30 dB gain and has identical 1500 ohm input and output impedances. For extremely high gain then, similar units can be cascaded up until an output voltage of 10 volts is obtained. This amplifier is also quite wideband, and with the transistors specified, the gain is essentially flat up to about 1 MHz.

Fig. 4. The gain of this wideband amplifier may be controlled by the value of the feedback resistor Rr. The 10K resistor shown here provides more than 30 dB gain from 10 Hz to 17 MHz. Q1 and Q2 are 2N2188, SK3006, GE-9 or HEP-2.

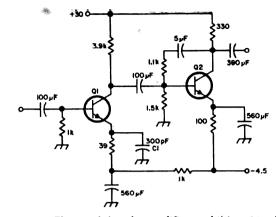

Fig. 5. This wideband amplifier exhibits 26 dB gain from 5 Hz to over 30 MHz and will deliver a 7 volt signal into a 100 ohm load. Transistors Q1 and Q2 are 2N2218.

Wideband amplifiers

In the wideband amplifier shown in Fig. 4, the gain is controlled by the feedback resistor Rr. With a 10 kilohm feedback resistor, the gain is greater than 30 dB from 10 Hz to 17 MHz. When the resistor is completely removed from the circuit, the gain is greater than 50 dB up to about MHz, but the biasing of the input transistor becomes very critical to prevent signal distortion. Note that the large electrolytic coupling capacitors should be paralleled with smaller capacitors that have good high frequency characteristics.

Another wideband amplifier is illustrated in Fig. 5; this amplifier has a frequency response from 5 Hz to over 30 MHz. The voltage gain over this range is 26 dB and the amplifier will deliver an undistorted 7 volt sine wave into a 100 ohm load. This circuit has excellent stability and linearity, and by adjusting the bias and emitter bypass capacitor C1 experimentally, the frequency response may be increased up to 50 MHz.

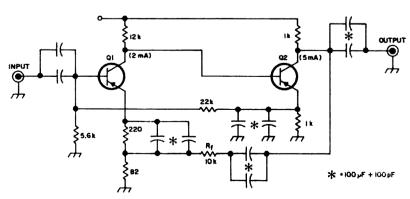

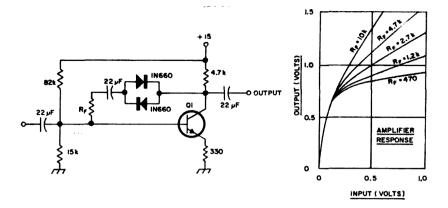

Fig. 6. The gain of this amplifier is controlled by the nonlinear feedback provided by two back to back diodes and the value of the feedback resistor R_f. Q1 is a 2N706, 2N708, 2N3394 or HEP-50.

Gain controlled amplifiers

It is a well known fact that the gain characteristics of an amplifier may be shaped by applying nonlinear feedback. In the amplifier of Fig. 6, the nonlinear feedback is furnished by two back to back diodes in the collector to base feedback path. Whenever the signal at the collector is high enough to forward bias the diodes (greater than approximately 0.6 volts peak to peak), negative feedback occurs and the gain of the amplifier is reduced. The gain of the stage may be further controlled by the value of the feedback resistor (Rr) as shown in the amplifier response curve. If it is desirable to have the nonlinearity occur at a higher level (greater than 0.6 volts peak to peak), more than one diode may be added to each leg of the feedback network. For lower levels, germanium diodes may be substituted for the silicon diodes specified in the schematic. With the germanium diodes in the feedback path, nonlinearity will occur when the signal is greater than about 0.1 volts peak to peak.

A voltage controlled, variable gain amplifier has many applications in automatic volume control, amplitude modulation and

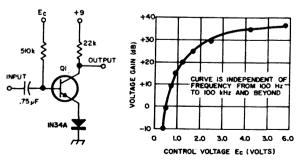

Fig. 7. Voltage controlled amplifier uses the varying impedance of a germanium diode in the emitter circuit to control gain. Transistor QI may be a 2N696, 2N3564, SK3019, GE-10 or HEP-54.

remote gain adjustment circuits. The only difference between the circuit shown in Fig. 7 and a standard common emitter amplifier is that a 1N34A diode is used in place of the emitter resistor. In an amplifier of this type, the gain of the stage is critically dependent upon the impedance of the emitter circuit. Since the impedance of the diode varies with the amount of current through it, the gain of the stage depends upon the transistor emitter current. The 1N34A was chosen because it provides an extremely wide impedance variation with a relatively gradual rate of change. This diode typically exhibits an impedance range from 15000 ohms at low levels to 200 ohms or less with high currents. The slow rate of impedance change is required to minimize distortion. This circuit is useful in ALC and AGC circuits, feedback regulation and other cases where wide dynamic range and instant response are required.

Preamplifiers

The simple low cost preamplifier in Fig. 8 provides extremely flat response from 10

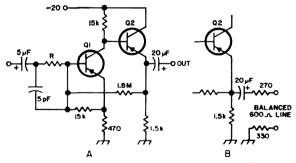

Fig. 8. High impedance preamplifier provides up to 1.2 megohms input impedance; the exact value depends upon the build-out resistor R. Both Q1 and Q2 should be a 2N2613, 2N2614, 2N2953, SK3004, GE-2 or HEP-254. A balanced output for reduced hum and noise may be obtained by using the padded output in B.

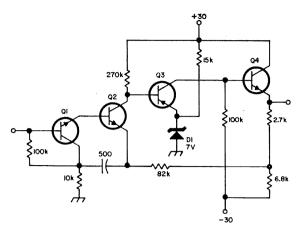

Fig. 9. This preamplifier provides II dB gain from 0.5 Hz to 2 MHz and has an input impedance of 32 megohms. Transistors QI, Q2 and Q4 are 2N338, SK3020, or HEP-53; Q3 is a 2N328, GE-2 or HEP-52.

Hz to 30 kHz and at the same time exhibits an input impedance up to 1.2 megohms. The input impedance of the first transistor with the unbypassed emitter resistor is on the order of 50,000 ohms; by including the build-out resistor R in the circuit, the input impedance may be increased up to 1.2 megohms. Without R in the circuit, the voltage gain is approximately 15. As the value of R is increased, the voltage gain decreases and the entire circuit exhibits unity gain when the value of R is 1.2 megohms.

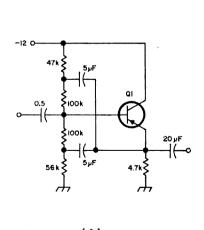

The output impedance of this simple preamplifier is particularly low, so it may be used for driving all types of circuits. Harmonic and intermodulation distortion are very low if 600 ohm circuits are connected across the output. It will also drive small 8 ohm speakers, but the distortion will be quite a bit higher.

The basic circuit provides an unbalanced output which should be suitable for most applications, but where hum and noise are a problem with balanced 600 ohm systems, the balanced output of Fig. 8B may be used. This pad adds a total of 6 dB loss in the output, but it does get rid of the hum and noise.

The four transistor preamplifier illustrated in Fig. 9 exhibits an input impedance of 32 megohms and provides 11 dB gain from 0.5 Hz to 2 kHz. The high input impedance of this amplifier is a function of the two negative feedback loops; one from the emitter of Q2 to the collector of Q1, the other from the junction of the 2.7k and 6.8k resistors in the emitter of Q4 to the emitter of Q2. The output impedance of this amplifier is 20 ohms so it may be used for driving many types of circuits.

In many cases an amplifier with an input impedance approaching that of a VTVM is required to keep circuit loading to a minimum. The amplifier of Fig. 10 more than meets these requirements; it provides up to 20 megohms input impedance, develops 1 volt rms across a 3300 ohm load and exhibits a frequency response from 10 Hz to 200 kHz.

The development of this circuit started

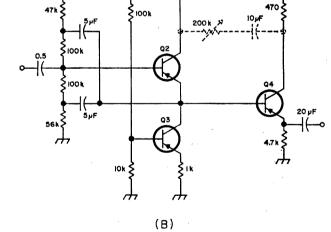

Fig. 10. This high impedance preamplifier provides up to 20 megohms input impedance and has a frequency response from 10 Hz to 200 kHz. Circuit B was developed from circuit A by replacing the emitter resistor in A with Q3 and adding an emitter follower to reduce loading. The input impedance is further increased by the components shown by the dashed line. All transistors are 2N2188, SK3005, GE-9 or HEP-2.

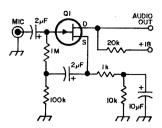

Fig. 11. Microphone amplifier using a field effect transistor has an input impedance of 5 megohms. Q1 is a 2N4360, TIM12, U-112 or U-110. By reversing the polarity of the supply voltage, a 2N3820, MPF-104 or HEP-801 may be used.

with the circuit shown in A. Here conventional bootstrapping was used on a basic emitter follower circuit to eliminate the shunting effect of the base bias resistors. When a transistor with a current gain of 100 was used, the input impedance was measured at 200K with a 3300 ohm load. A significant increase in input impedance may be obtained by replacing the emitter resistor of Q1 with the collector resistance of Q2 as shown in B. To keep the loading as light as possible on the emitter of Q1, an emitter follower (Q3) is used. With this circuit, the input impedance is slightly over 1 megohm with a 3300 ohm load.

The input impedance of this circuit may be further increased with the addition of the components shown by the dashed lines. However, if this positive feedback is overdone, the circuit will oscillate. If, on the other hand, the 200k feedback pot is carefully adjusted, the input impedance may be raised to 20 megohms or so before instability occurs.

The high impedance microphone pream-

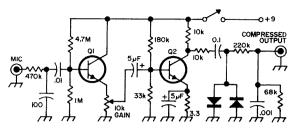

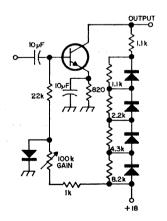

Fig. 12. Two stage clipper/preamp will increase the talk power of your rig. Transistors QI and Q2 are 2N1304, 2N2926, 2N3391, SK3011, or HEP 54. The diodes are IN456 or HEP-158.

plifier illustrated in Fig. 11 makes use of the inherently high input impedance of field effect transistors. This impedance is raised still higher by the use of the 2 µF bootstrap capacitor from source to gate; in this case to about 5 megohms. This circuit's output impedance of 2k is suitable for driving other FET's or conventional junction transistors.

Clipper/preamplifier

The microphone clipper/preamp shown in Fig. 12 is very simple to construct and allows you to stay as far away from the mike as you like; it does a very good job of beefing up weak audio signals. It was designed primarily for high impedance dynamic microphones, but may be used with other mikes with slightly less gain. It provides up to 10 dB gain on low level audio signals and since it uses a minimum of parts, may be easily constructed in a small minibox.

Although the best way to adjust a clipper such as this is with an oscilloscope the gain control may be set so that the final

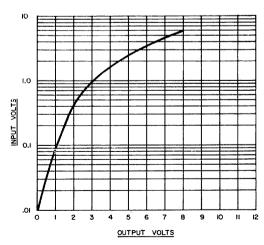

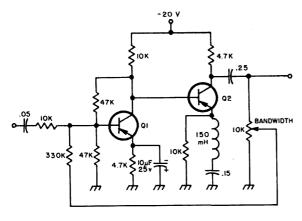

Fig. 13. This simple dynamic range compressor provides more than 50 dB range; it exhibits gain with a 20 millivolt signal but will not saturate with input voltages up to 6 or 7 volts. All the diodes are IN914; transistor QI should be a 2N2926, 2N3391, SK3010, GE-8 or HEP-54.

01, 02 - 2N465, 2N2953, SK3004

Fig. 14. This simple audio bandpass filter may be narrowed to the limits of unintelligibility. At a bandwidth of 80 Hz, it provides about 20 dB gain. The input is connected to the phone jack on your receiver while headphones are connected across the output.

audio stage (of your transmitter) approaches saturation on a steady whistle (into a dummy load please); this will approach optimum adjustment. A final check should be an on the air report from a nearby station so you can determine the approximate range settings appropriate for your particular transmitte.

Compression amplifier

The compession amplifier illustrated in Fig. 13 provides a minimum output signal with only 20 millivolts (0.02 volts) input,

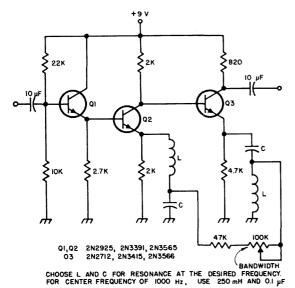

Fig. 15. This three stage audio filter uses two series resonant circuits to provide a very narrow audio passband. The Q of the circuits, and therefore the bandwidth, is controlled by the amount of feedback.

but will not saturate with input voltages up to 6 or 7 volts. The secret to its operation of course lays in the diodes connected across the collector load resistors. As the signal output is increased, the diodes conduct one by one and lower the resistance of the collector load. Although this amplifier has a minimum gain of 1 and a maximum gain of 15 with the components shown in the schematic, the gain characteristics may be made to follow other curves by the proper selection of load resistors and diodes.

Audio filters

The two transistor audio filter in Fig. 14 uses positive feedback to increase the Q of an inexpensive LC circuit to a very high degree. At a bandwidth of 80 Hz for example, this circuit provides 20 dB gain and furthermore, the bandwidth may be decreased to the limit of intelligibility. The gain stability is increased in this amplifier by the use of negative feedback from collector to base of Q1; this also serves to reduce the output impedance and increase the power transfer to the succeeding stage.

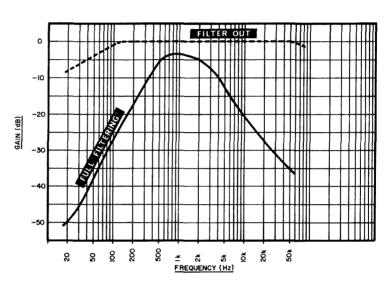

At frequencies far removed from the resonant LC circuit in the emitter of Q2, the emitter impedance is essentially that of the 10k emitter resistor. As resonance however, the low series impedance of the LC network predominates and increases the gain of the stage. Since the output signal is in phase with the input signal, the feedback through the 10k bandwidth pot and 330k resistor is regenerative. As the gain of the amplifier increases near resonance, the output voltage rises sharply and transforms the low Q circuit into a highly selective audio amplifier.

The proper value for the 330k feedback resistor varies from transistor to transistor, so the value of this resistor should be chosen experimentally. This resistor should just produce oscillation when the bandwidth pot is advanced to the maximum feedback position. To use this circuit, simply plug it into the phone jack on your receiver, connect a pair of headphones across the output and advance the bandwidth control until a whistle is heard; back off a little on the bandwidth and it's ready to operate.

The audio filter illustrated in Fig. 15 is somewhat similar to the one in Fig. 14 except that the passband has a better shape

22k OUT OUT OUT PU

Fig. 16. This highly versatile audio filter may be used to completely shape the audio spectrum of your receiver or transmitter; it may be used with the filters out, or with the variable low- and high-pass filter networks connected. All the transistors are low cost audio types such as the 2N1305, 2N1380, 2N2613, GE-2 or HEP-253.

factor because two series resonant LC circuits are used. Here again feedback is used to raise the Q of the resonant circuits to a very high value. The 47k resistor in the feedback line should be adjusted experimentally so that the circuit will just oscillate when the 100k bandwidth pot is shorted out (maximum clockwise position). Although the LC values shown in the schematic are for a center frequency of approximately 1000 Hz, other values may be used for

Fig. 17. Resistance-capacitance tone controls are usually not too satisfactory with junction transistors because of heavy loading. The high impedance characteristics of the FET eliminates this problem with no loss in the dynamic range of the tone control. Q1 is a 2N2943, 2N3820, MPF-105 or HEP-801.

other center frequencies.

One of the problems in amateur SSB communications is that the audio spectrum of the speech amplifier should be shaped so that it amplifies only those signals between about 300 and 3000 Hz. This can be accomplished by high-Q tuned circuits, but the inductors required are quite large and expensive. A simpler approach is to use the adjustable audio bandpass filter shown in Fig. 16. When the high- and low-pass filter of this amplifier are out of the circuit, it is flat within 1 dB from 100 Hz to 50 kHz. With the filters in the circuit, the audio may be shaped between the limits shown in Fig. 16.

Tone control

Audio tone controls using conventional junction transistors are difficult to build because the low input impedance of these devices seriously limits the tone control's dynamic range. An obvious solution to this problem lies in applying the inherently high input impedance of the field effect transistor. The tone control illustrated in Fig. 17 should be familiar to old vacuum tube hands; it is a straightforward tone control for both treble and bass using a modern FET in place of a thermionic triode.

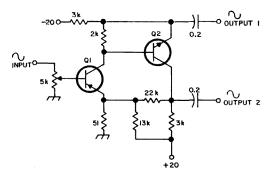

Fig. 18. This phase splitting circuit provides two out of phase signals for driving a push pull amplifier without an expensive transformer. The gain of the stage as shown is 150, but this may be adjusted by changing the value of the 22K feedback resistor. Q1 and Q2 are a complimentary pair such as the 2N652 and 2N388 or 2N2430 and 2N2706.

Phase splitter

The simple phase splitting circuit in Fig. 18 is a two stage direct coupled amplifier connected as a complementary pair with feedback and illustrates a novel way of obtaining out of phase driving signals for a push pull amplifier without an expensive transformer. The input transistor is a common emitter voltage amplifier with its collector tied directly to the base of Q2. The 3k resistor in the emitter of Q2 provides bias for this transistor but does not cause regeneration because it is common to both the base and emitter. The 13k resistor sets the overall circuit bias and its value is chosen so that the collector and emitter of Q2 are at the desired operating level. The 22k feedback resistor provides negative feed-

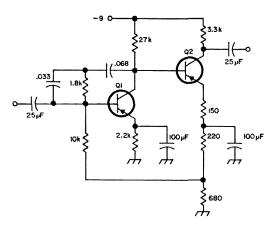

Fig. 19. This phono preamplifier uses frequency selective feedback between the collector and base of Q1 to obtain proper equalization during playback. Transistors Q1 and Q2 are 2N584, SK3003, GE-2 or HEP-254.

back to the emitter of Q1 and determines the gain of the circuit. In this case 22 kilohms was chosen to set the gain at 150, but other values of gain may be obtained by adjusting the value of this resistor.

Equalized audio amplifier

The equalized audio amplifier shown in Fig. 19 is a two stage direct coupled audio amplifier with a frequency selective feedback path. It is particularly suitable for boosting and equalizing the signal from a ceramic phono pickup to obtain a flat output of sufficient level to drive an audio power amplifier.

When playing a record, the output from the pickup is proportional to the force to which the stylus is subjected when tracing the groove. In fact, the open circuit voltage across the pickup is approximately proportional to the logarithm of the frequency with reference to the recorded amplitude. If the pickup is loaded with a very high impedance on the order of one or two megohms, the output versus input is nearly the inverse of the recording characteristic; therefore, the equalization is automatic.

However, it is not always possible to load the pickup with a very high impedance circuit, especially when transistors are used

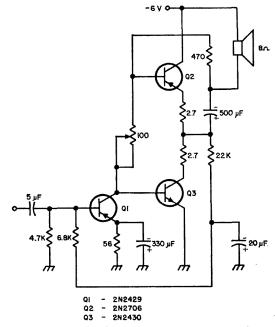

Fig. 20. This complimentary amplifier provides up to 220 mW output with a frequency response from 90 Hz to 12.5 kHz. Although matched transistors are not required for Q2 and Q3, they are available as the 2N2707.

in the preamplifier. Resistive pads may be used to increase the input impedance, but they greatly reduce stage gain and increase problems with signal to noise ratios.

In the amplifier of Fig. 19 equalization is obtained by a frequency selective feedback path between the collector and base of Q1. Stabilization at dc is provided by the direct coupling between Q1 and Q2 and the current feedback path through the 10 ohm resistor in the base of Q1. In addition, more negative feedback is provided by the unbypassed emitter resistor in the second stage.

Complementary power amplifiers

The small transformerless complementary amplifier illustrated in Fig. 20 provides an output of 220 mW with an input of only 40 microamps. The transistors in the single ended class B output stage are used in the common collector configuration and are biased by a resistive voltage divider and the driver transistor circuit. The emitter resistors in the output stage provide adequate temperature stability and are established by cut and try, but a value of 2.7 ohms seems to offer a good compromise. In adjusting this amplifier, the 100 ohm pot should be adjusted so that the idling current of the output transistor is on the order of 2.5 mA; this will insure a minimum of crossover distortion. When properly adjusted, this amplifier will exhibit a ±3

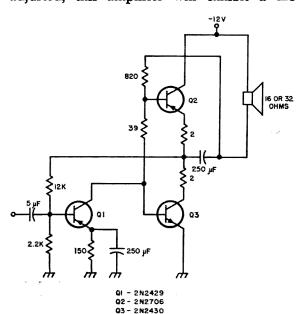

Fig. 21. This 470 mW complementary audio amplifier exhibits less than 2% distortion and is flat within 3 dB from 15 Hz to 130 kHz.

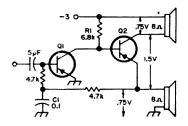

Fig. 22. An audio power amplifier with push pull output using a single transistor in the final stage may be obtained with this simple circuit. Only about 50 mW is available from this amplifier, but the gain is flat up to 30 kHz. Both Q1 and Q2 should be germanium audio transistors such as the 2N215, 2N404, 2N2953, SK3004 or HEP-253.

dB frequency response from 90 Hz to 12.5 kHz and distortion of 4% at 120 mW input and 10% at 220 mW input.

Another complementary audio amplifier is shown in Fig. 21. This power stage provides 470 mW output and utilizes both ac and dc feedback to minimize distortion and extend frequency response. Although unmatched transistors are not required for the proper operation of this amplifier, a set of matched transistors is available as the 2N2707; the cost of the matched pair is only several cents more than the total separate costs of a 2N2706 and 2N2430. This very useful amplifier is flat ±3 dB from 15 Hz to 130 kHz, exhibits an input impedance of 750 ohms and produces less than 2% distortion at 470 mW output.

Single transistor push pull

The amplifiers illustrated in Figs. 22 and 23 illustrate how a quasi-push-pull output may be taken from a single transistor.

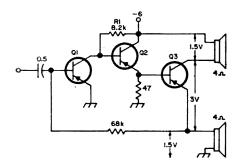

Fig. 23. A larger power version of the single transistor push pull circuit of Fig. 22 is shown here. The operating characteristics are similar to the 50mW circuit except that approximately I watt may be obtained. Transistors QI and Q2 are 2N215, 2N404, 2N2953, SK3004 or HEP-253; Q3 is a 2N554, 2N1032, 2N1666, SK3009 or HEP-232.

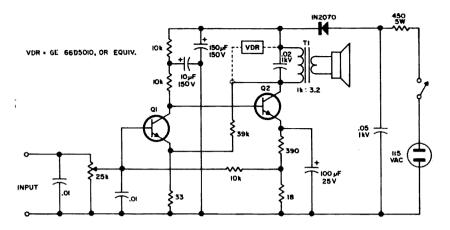

Fig. 24. This line operated audio power amplifier provides about 500 mW output with an 80 millivolt input signal. Q1 is a 2N3565, SE4002, SK3020 or HEP-54; Q2 is a 2N3916 or SE7005.

These amplifiers are dc connected, thereby eliminating many components, while at the same time assuring excellent low frequency response.

In the circuit in Fig. 22, the first transistor serves as both an ac driver and part of the dc bias system. Although the values shown in the schematic were selected for optimum results, the 6800 ohm biasing resistor (R1) should be adjusted experimentally to obtain equal voltages across the collector and emitter loads as illustrated in the schematic.

The frequency response of this amplifier may be adjusted by changing the value of the 0.05 µF capacitor (C1). When this capacitor is left completely out of the circuit, the heavy negative feedback around the circuit provides a frequency response that is flat from dc (with the input capacitor shorted) to 30 kHz. However, under these conditions, the gain is only about 35 dB. The maximum power output available from this circuit is on the order of 50 mW; above this level severe clipping occurs with noticeable audible distortion.

A higher power circuit that exhibits essentially the same characteristics is illustrated in Fig. 23. With properly heat sinked transistors, this unit provides usable outputs up to one watt. As with the lower power circuit, the bias resistor (R1) should be adjusted to provide equal voltages across the emitter and collector loads shown in the schematic.

The input impedance of both these circuits is on the order of several thousand ohms, so they may be easily driven by other transistor circuits. Although two separate speakers are shown as the output load, the load could just as easily be two separate transformer windings.

Line operated amplifiers

The line operated one watt amplifier in Fig. 24 provides about 500 mW output with an 80 mV input signal. The use of transistors with high collector to emitter voltage ratings permits the use of a transformerless power supply operating directly from the 115 volt ac line. To prevent damage to Q2 in the event of transient voltage spikes on the line, a voltage dependent resistor (VDR) such as a General Electric Thyrector or Motorola Thyristor should be connected across the primary of the output transformer.

Another line operated power amplifier is illustrated in Fig. 25. This amplifier is

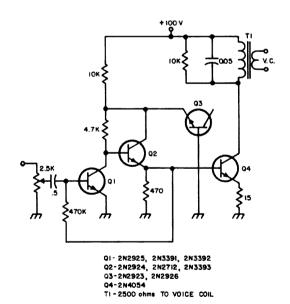

Fig. 25. High performance with low cost is obtained with this line operated audio power amplifier because expensive electrolytic capacitors are eliminated by direct coupling between stages. This circuit delivers I watt to the speaker with 3 mW input.

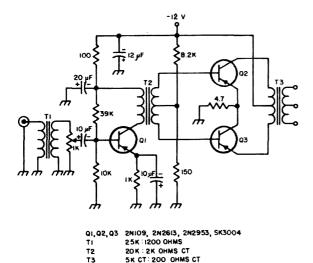

Fig. 26. This 100 mW modulator may be used to collector modulate transmitters up to about 200 mW or to base modulate somewhat larger power amplifiers. Good performance with a minimum of components is obtained by transformer coupling between stages.

based on the use of a high voltage plastic transistor, the 2N4054. The circuit delivers one watt of audio power to a speaker with about 3 millivolts input signal; at this power level the total harmonic distortion at 1 kHz is less than 10%. The key to its low cost performance is the fact that direct coupling is used, thereby eliminating the need for expensive electrolytic capacitors.

Modulators

The 100 milliwatt modulator illustrated in Fig. 26 is suitable for collector modulating small transistor transmitters up to about 200 milliwatts. It may also be used for base modulating somewhat larger transmit-

ters. The circuit is relatively straight forward, with a single audio amplifier driving the class B push pull power stage through a small transformer. To modulate the collector of a small transmitter, simply run the collector voltage supply through the secondary of the "moduation" transformer, in this case a low cost 5k:200 ohm audio transformer.

The 5 watt modulator shown in Fig. 27 may be used to modulate transmitters with up to 10 watts input. The use of low cost, high gain silicon transistors and efficient transformer coupling significantly decreases the complexity of the circuit. Usually many more transistors are required to obtain five watts of audio with a microphone input. Although this modulator was designed for a ceramic or crystal microphone, it may be used with dynamic types with slightly less gain. This circuit exhibits extremely low distortion characteristics, and when used to collector modulate a ten watt transistor transmitter, produces extremely clear and crisp audio.

The transistorized 25 watt modulator shown in Fig. 28 is not much different from other types which have been described, but with three transformers it is somewhat more efficient than most. The transformers are readily available commercial models which may be obtained from most suppliers. However, transformer T2 must have a center tap on the secondary; this is easily accomplished by unwinding 46 turns from the outside winding, bringing out a center tap at this point and rewinding. Impedance matching to the rf amplifier is accomplished by adjusting the rf output loading network.

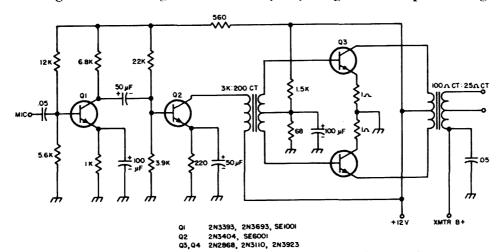

Fig. 27. 5 watt modulator for transmitters up to 10 watts input. High gain silicon transistors and transformer coupling increase performance at decreased circuit complexity.

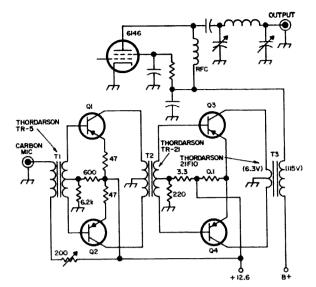

Fig. 28. 25 watt modulator uses readily available commercial transformers. Transistors Q1 and Q2 are 2N1172, 2N301, 2N1560, SK3009, GE-9 or HEP-232; Q3 and Q4 are 2N174, 2N278, SK3012, GE-4 or HEP-233.

The frequency response of this circuit is quite good and is essentially flat from 200 Hz to 7 kHz.

Circuits for Receivers

Injection oscillator

If you are interested in building a dual conversion receiver for single channel operation on MARS, 2 meter FM or WWV, the single oscillator circuit which provides two outputs illustrated in Fig. 29 should be of interest. This single oscillator circuit results in a reduction of components without sacrificing receiver performance. Basically it consists of a conventional common base transistor oscillator which provides the injection voltage for the second mixer. The output of the oscillator is fed into a diode harmonic generator and resonant tank which is tuned to the desired harmonic; this harmonic is used for injection into the first mixer. For example, for a dual conversion 15 MHz WWV receiver with a 455 kHz if, a 3636 kHz cystal would be used along with its third harmonic at 10.908 MHz. The 10.908 MHz signal would be mixed with the 15 MHz WWV signal in the first mixer to provide an output at 4092 MHz; this signal would in turn be mixed with the 3636 kHz oscillator output in the second

mixer to provide the 455 kHz if. The only consideration in choosing the crystal and harmonic frequencies is that only odd harmonics should be used. This is because when even harmonics are used in this scheme, poor second if image rejection will be a problem.

In most receivers the oscillator injection frequencies are below that of the signal frequencies. This is usually desirable since it results in a lower first *if* frequency which will provide better image rejection. In this case the necessary crystal frequency may be found from the following formula:

$$f_{\circ} = \frac{f_{\bullet} - f_{\circ f}}{h+1}$$

Where: f. = Crystal frequency

f. = Signal frequency

 $f_{ij} = if$ frequency

h = Harmonic to which diode tank circuit is tuned.

In those cases where it might be desirable to have the injection frequencies higher than the signal frequencies, the following formula may be used:

$$f_0 = \frac{f_0 - f_{if}}{h - 1}$$

BFO's

The simple BFO in Fig. 30 may be added to an existing receiver with a minimum of cost and effort. Essentially it is a tuned collector oscillator with an *if* transformer being used for the tuned circuit inductance. Just pick a transformer that is compatible with the *if* in your receiver; it doesn't make any difference to the transistor. Anything between 85 kHz and 1600 kHz will work

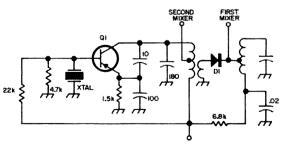

Fig. 29. Single oscillator and diode provide two injection frequencies for dual conversion receivers. Transistor QI is a 2N1745, 2N2188, TIM10, GE-9 or HEP-2; the diode should be a IN82A or similar.

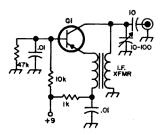

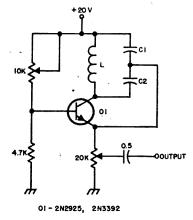

Fig. 30. This beat frequency oscillator may be added to existing receivers with a minimum of difficulty. The BFO frequency is determined by the if transformer which provides feedback from collector to emitter. Transistor QI should be a 2N384, 2N1749, 2N2362, TIMIO, SK3008, GE-9 or HEP-2.

well in this circuit. Before you can use the transformer though, remove all of the fixed tuning capacitors from the unit; usually these are readily available on the bottom of the transformer. If the circuit does not oscillate when voltage is applied, reverse the transformer leads going to the emitter of the transistor. To connect the BFO into the receiver, run a piece of small coaxial cable from the BFO output to the base (or grid) of the detector. In some cases sufficient injection will be obtained by just placing the coax lead in the immediate vicinity of the detector. Adjust the core in the BFO transformer so that the variable tuning capacitor allows the BFO output to swing to either side of the receiver if; then the variable capacitor will operate as a pitch control.

FREQUENCY	CI	C2	L
50 kHz	3500 pf	1500 pf	IO mH
80 kHz	2200 pf	910 pf	6.2 mH
100 kHz	1800 pf	750 pf	4.7 mH
200 kHz	910 pf	390 pf	2.2 mH
455 kHz	390 pf	160 pf	I mH
1000 kHz	180 pf	75 pf	0.47 mH

Fig.:-31. This simple circuit provides an extremely stable BFO. The frequency of oscillation may be tailered to your needs by simply choosing the proper tank components listed in the table.

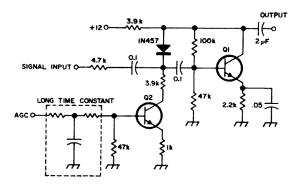

Fig. 32. This super AGC circuit only requires two transistors to obtain up to 60 dB of control. Q1 and Q2 are 2N1613 or HEP-254.

The circuit illustrated in Fig. 31 represents a temperature stable Colpitts oscillator which is very useful as a BFO. This oscillator utilizes an inexpensive silicon planar transistor and is exceptionally stable over wide ranges in temperature. In addition, it is characterized by a large output amplitude (10 volts peak to peak) and low harmonic distortion. In addition to duties as a beat frequency oscillator, this circuit is useful where a stable signal source is required up to several MHz. The 20k emitter pot is an output level control; the 10k pot in the base bias leg is used to adjust the base bias for maximum amplitude output.

AGC circuit

The super AGC circuit shown in Fig. 32 requires only two transistors to obtain 60 dB of control, while maintaining low distortion and power requirements. When a signal appears at the input with its corresponding AGC signal on the input of the long time constant circuit, Q1 conducts and causes current to flow through the diode. This current flow lowers the impedance of the diode and provides a low impedance path between the amplified signal at the collector of Q2 and the input signal at its base. When the diode conducts heavily, there is nearly 100% feedback and the gain of this stage is nearly unity. In addition, the input impedance of the stage becomes very low and results in a large voltage drop across the series connected 4700ohm resistor.

When the collector current of Q1 is reduced to zero, the feedback through the diode is negligible and the gain and input impedance of Q2 is the same as that of a standard common emitter amplifier. With

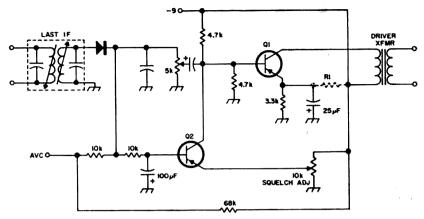

Fig. 33. This simple squelch circuit may be added to any transistorized receiver with only minor changes; in most receivers only four additional components are required, two resistors, a capacitor and a transistor. Q1 is an existing transistor in the receiver; Q2 is a 2N404, 2N2953, SK3004, GE-2 or HEP-254.

the constants shown in the schematic, a 60 dB control range is provided by a 0 to 100 μ A AGC input. To increase this range, high gain transistors and a higher voltage power supply must be used.

Squelch circuits

The simple, but positively acting squelch circuit in Fig. 33 may be added to any transistorized receiver with only minor changes in the audio section and four additional components. Without an input signal, normal forward bias to the *if* amplifier flows in the AGC line. A portion of this bias voltage is applied to the base of Q2 through the 10K ohm squelch adjust. This voltage biases Q2 into full conduction with the

squelch control pot determining the degree. When Q2 is saturated, base bias for Q1 is diverted to ground so the driver cannot amplify incoming noise and the speaker is quiet. When a carrier large enough to cut off Q2 is received, Q1 conducts and amplifies normally. The $100~\mu F$ filter capacitor in the base of Q2 removes all but the AGC signal coming from the detector.

To make the squelch less sensitive to large noise pulses, resistor R1 will ensure that transistor Q1 will be cut off until rf operates the squelch. The value of this resistor should be determined experimentally, since its value depends upon the type of transistor used in this stage.

Another simple squelch circuit is illustrated in Fig. 34. When there is no signal

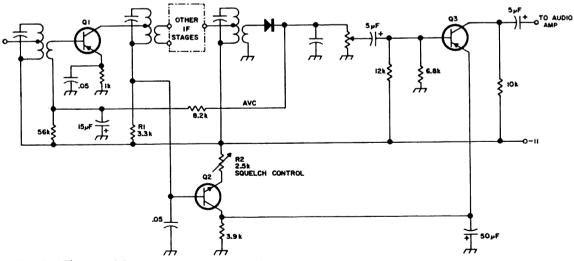

Fig. 34. This squelch circuit is very versatile and is capable of squelching out a 300 μ V signal and still maintain control down to less than 1 μ V. With the 2.5K pot set to squelch out a signal, approximately 3 dB increase in received signal will override the squelch. Q2 is a 2N1304, GE-5 or SK3011; Q3 is a 2N1274; GE-2 or HEP-254.

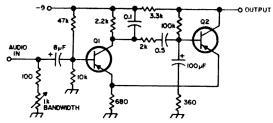

Fig. 35. This audio filter uses a 1000 Hz Wien bridge circuit to provide bandwidths from 70 to 600 Hz wide. Q1 and Q2 are 2N408, 2N2613, SK3004, GE-2 or HEP-254.

coming into the receiver, the AGC controlled *if* amplifier Q1 is operating at maximum gain. Under this condition the voltage drop across R1 is also maximum and is used to turn Q2 on. The current through Q2 is determined by the squelch control, R2. If R2 is set so that the current flow through Q3 causes the voltage drop across the 3.9k emitter resistor to be greater than the base voltage of Q3, it will be turned off. Under these conditions, there will be no output from Q3 and the receiver will be quiet.

When a signal is picked up by the receiver and the AGC is operating, the current through Q1 is reduced according to the signal strength of the received signal. This in turn reduces the voltage across R1, reduces the current through Q2 and lowers the voltage on the emitter of Q3. When the emitter to base junction of Q3 is forward

biased, the stage turns on and results in an output to the audio amplifier.

This circuit is very versatile and is capable of squelching out a 300 µV signal into the receiver and still maintain control down to less than 1 µV. In some cases there may be some audio distortion between the on and off conditions of Q3, depending upon the setting of the audio gain control. This distortion is not ordinarily objectionable however and when the signal is several times greater than that required to just trigger the squelch, it is not present.

Selective audio amplifier

Selective transistor amplifiers are very helpful in sorting out stations from the QRM that plagues our HF bands. They are also quite helpful in VHF and UHF work for effectively narrowing the bandwidth of the receiver. This is because as the bandwidth is narrowed, the noise in the receiving bandpass is reduced accordingly.

In the selective transistor amplifier illustrated in Fig. 35, the frequency selected is determined by a modified Wien bridge circuit in the collector of the first transistor. Although the constants shown in this circuit are for a center frequency of 1000 Hz, other frequencies may be selected by the proper choice of bridge components. The bandwidth of this circuit is determined

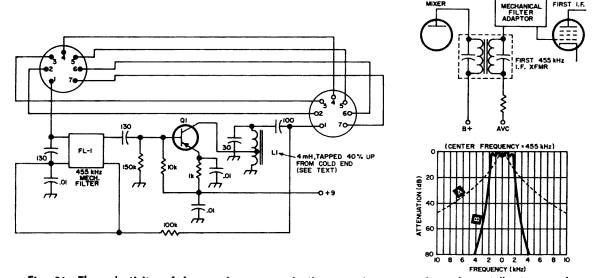

Fig. 36. The selectivity of inexpensive communications receivers may be substantially increased by the addition of this mechanical filter adapter. The transistor is used to make up for the 10 dB loss through the filter. The typical passband of a receiver without the filter is shown by A in the frequency response curve; the mechanical filter adapter results in curve B, QI should be a 2N1638, 2N1727, SK3008 or HEP-3.

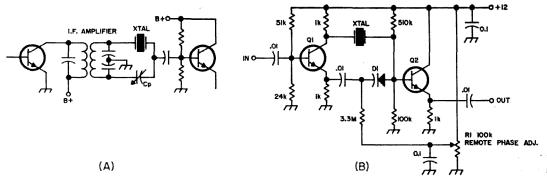

Fig. 37. Usually the crystal filter circuit in a receiver (A) must be physically located so the phasing capacitor (C_p) is accessible to the front panel. By using the varactor phased filter in B, the crystal may be located in any convenient location. Q1 and Q2 are 2N3478, 2N3564, 2N3707, 40236 or HEP-50; D1 is a 20 pF varactor such as the 1N954 or TRW V20.

by the value of the input load resistor, but with the resistors shown, it may be varied between 70 and 600 Hz.

Mechanical filter adapter

With the heavy ORM that is rampant on today's high frequency ham bands, the selectivity of many of the lower cost communications receivers leaves a great deal to be desired. In fact, in many cases the selectivity of these receivers is hopelessly inadequate. Adding a Q multiplier or a simple crystal filter will help to some extent, but these devices simply narrow the peak of the if response curve. Although this is quite suitable for CW work, it is of little help in separating SSB and AM stations. A much more useful improvement is the addition of a mechanical filter to the receiver if. Unlike simple LC circuits, the mechanical filter closely approximates the ideal bandpass response curve.

Wiring this filter into a receiver could require some pretty extensive rework, but by using the transistorized mechanical filter adapter illustated in Fig. 36, it may be simply plugged into the first if amplifier tube socket. The actual circuit itself is very straightforward; the simple transistor amplifier makes up for the 10 dB of loss through the mechanical filter. Coupling the output of the transistor to the grid of the first if tube is accomplished with the 4 mH coil. This may be made by winding 100 turns of number 36 on a cup core r toroid (tapped at 40 turns) or the primary of an inexpensive 455 kHz if transformer may be used.

Layout of the circuit is not at all critical except that care should be taken to make

sure that there is no leakage around the mechanical filter and amplifier. To this end the plate lead of the if tube should be shielded. Although the base layout shown in the schematic is for a 6BA6 tube, this adapter may be used with any if tube by simply placing the mechanical filter in the grid lead. Packaging this device is quite simple too; just mount an appropriate tube socket on top of a plug-in can (Vector G2.1-8-4), build the circuitry inside, plug it in the receiver tube socket and pick the weak signals out of the QRM.

Tunable crystal filter

One of the problems encountered when installing a crystal filter in a receiver for added selectivity is the fact that the unit must be installed physically close to the front panel so that the phasing control (C_p) is accessible. This problem is neatly solved by using the varactor tuned unit shown in Fig. 37. In this circuit, the crystal is phased by the varactor diode which may be remotely controlled by the variable resistor R1. The circuit may be used for any if from 100 kHz to 1500 kHz by simply selecting a crystal which is resonant at the desired frequency. In addition, the filter may be completely removed from the system by simply forward biasing the diode.

Cascode amplifiers

One of the big advantages of the cascode rf amplifier is that in the high frequency range it does not require neutralization. In the cascode circuit shown in Fig. 38, two transistors are connected so that the mismatch between them reduces internal

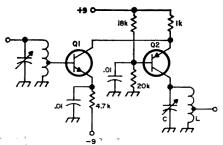

Fig. 38. This cascoda amplifier is extremely useful because it provides high gain without the need for neutralization. Q1 is a 2N918, 2N3464, 2N3478, MPS918, 40235 or HEP-56; Q2 is a 2N1742, 2N2398, 2N2894, 2N3399, TIM10 or HEP-2.

feedback; therefore the input and output impedance of the circuit is essentially independent of the source and load.

In single transistor amplifiers the collector to base capacitance causes internal negative feedback that reduces amplifier gain at high frequencies. This feedback also causes the input and output impedances of the transistor to be dependent upon the value of the source and load impedances. Normally this negative feedback is neutralized out with a small amount of positive feedback external to the transistor. Unfortunately however, this process is long and tedious and often requires many adjustments.

The isolation between several similar stages is particularly important where more than one stage is used, because as a multi-

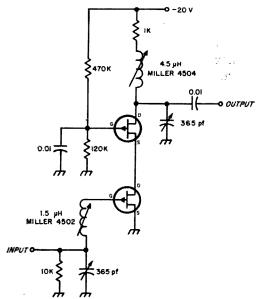

Fig. 39. This 30 MHz if stage uses two FET's connected in the cascode arrangement to provide 20 dB gain without neutralization; the bandwidth is 4 MHz. Both FET's in this circuit are 2N3819, MPF105 or TIS34. With a negative supply voltage, the 2N4360 or TIM12 would be suitable.

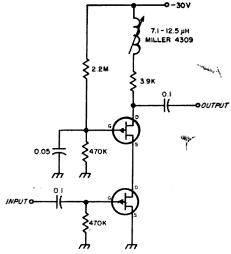

Fig. 40. This cascode video amplifier provides more than 6 MHz bandwidth with a voltage gain of 10. Both FET's are 2N3819, MPF105, TIS34 or HEP-801. A negative supply would permit the use of a 2N4360 or TIM12.

stage amplifier is being aligned, the tuning of one stage effects all the other stages. With the cascode rf amplifier, this shortcoming is overcome. Moreover, the gain of the cascode circuit is greater than the gain of a neutralized common-emitter stage with the same stability.

Since the emitter of Q1 is tied directly to the negative supply, the base can be connected directly to the output of the previous stage which is at ground potential. This eliminates a coupling capacitor and speeds up circuit recovery time after an overload. In addition, the gain of the stage may be controlled by varying the amount of current through Q1 (by adjusting the value of the negative supply).

The high gain cascode circuit shown in Fig. 38 uses two very inexpensive transistors to obtain 15 dB gain at 100 MHz with no neutralization; at lower frequencies the gain will be somewhat higher. No values are shown for the tuned circuits because they will be different for each application. However, dc biasing is usually the toughest part of any amateur transistor circuit design, and that is already done; all you have to do is put some tuned circuits in. The tap point on the input inductor should be chosen for best noise figure. The tap on the output inductor is chosen for maximum power gain.

Another somewhat different cascode circuit is illustrated in Fig. 39. This cascode 30 MHz if amplifier uses FET's and is

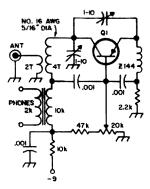

Fig. 41. This simple one transistor superregenerative receiver for two meters may be used for copying many local signals. With the components shown, this receiver will tune from about 90 to 150 MHz. It may be used on other frequencies by changing the inductor and capacitor as described in the text. Q1 is a 2N1742, 2N2398, 2N3399, TIM10, GE-9 or HEP-2.

characterized by a 20 dB power gain, bandwidth greater than 4 MHz, and all without the necessity for neutralization. For even more gain, these stages may be simply cascaded.

The cascode video amplifier shown in Fig. 40 is almost an exact replica of the vacuum tube circuit that was originally developed in the 1940's. Usually a single triode is avoided in wideband or video amplifiers because the input capacitance and its multiplication by device gain (called Miller effect) seriously loads the input capacitance is no longer multiplied by the gain of the device, but is limited to the input capacitance of the FET. With the shunt peaking

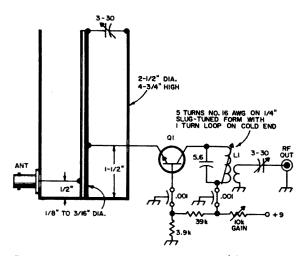

Fig. 42. Low noise two meter preamplifier uses a beer can cavity to provide excellent discriminatoin against nearby kilowatts. QI is a 2N3478, 2N356?. 2N3564, 40235 or SK3015

inductance shown (Miller 4309), this circuit is characterized by a voltage gain of 10 with a 3 dB bandwidth of over 6 MHz. The value of the inductance shown should work with most loads, but in some cases the bandwidth may be increased by changing its value slightly.

Two meter superregenerative receiver

The simple little receiver shown in Fig. 41 was designed primarily for the two meter band, but with appropriate changes in the input rf coils, it will work equally well on any frequency between 28 and 160 MHz. Basically, Q1 is a common base oscillating detector stage which quenches at about 25 kHz. The audio output from the detector is coupled across the transformer to the simple two stage audio amplifier. For more audio output, a 500 to 3.2 ohm transformer may be connected between Q3 and the speaker. The 20 kilohm pot should be adjusted for a total current drain of about 30 mA.

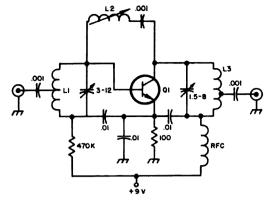

With the circuit constants shown in the diagram, this receiver will tune from about 90 to 150 MHz. To cover six meters, the tuning capacitor should be changed to a 15 pF unit and the number of turns on L2 increased to 6½. Since this is a regenerative receiver, it must be completely enclosed in a metal box to avoid the undesirable effects of hand capacity.

Two meter preamp

The two meter preamplifier of Fig. 42 uses inexpensive transistors in the common base configuration, yet provides noise figures that are nearly optimum for this band. The coaxial input cavity is easy to build and will provide more than adequate selectivity against your high powered neighbors on two. Although this input cavity may be built from scratch, the easiest approach is to use a spent beer can. Be careful when choosing the can though, some brewers are using aluminum cans wich are pretty difficult to solder. The whole amplifier may be mounted on a small piece of epoxy board and then the entire assembly attached to the outside of the cavity.

220 MHz rf amplifier

The 220 MHz rf amplifier shown in Fig. 43 exhibits about 17 dB gain, although the exact amount will depend upon the type of transistor used. Optimum operation for low-

- 3-1/2 TURNS NO 16, 1/4" DIAM, 1/2" LONG. TAPPED AT CENTER. 8-1/4 TURNS NO 24 ON 1/4" SLUG-TUNED FORM.

- 2N3478, 2N3564, 40235
- RFC 0.84 µH (OHMITE Z-220)

Fig. 43. Low noise 220 MHz preamplifier. This circuit will provide extremely high gain with low noise on the $1\frac{1}{4}$ meter band. Neutralization is controlled by inductor L2.

est noise figure also depends upon the transistor type, but usually will be in the vicinity of 6 volts collector voltage and 1 mA collector current. Unfortunately, this is usually not the same operating condition for maximum gain; maximum gain will occur at somewhat larger values of collector voltage and current. When this amplifier is set up, the 470k base bias resistor should be adjusted for the condition that you are looking for, whether it be minimum noise figure, maximum gain or a compromise between the two. Remember that for most practical receivers the noise figure will be dictated by the noise figure of the first rf stage; more gain can be added by another stage of amplification.

Circuits for Transmitters

Crystal oscillators

A compact untuned crystal oscillator is a very useful unit to have around the shack. The oscillator illustrated in Fig. 44 does not have any tuned circuits, so almost any crystal from 300 kHz up to 10 MHz will oscillate satisfactorily. It can be used for driving transmitters, as a signal source or for just testing crystals. In this circuit the first transistor is operating as an untuned crystal oscillator with the second transistor

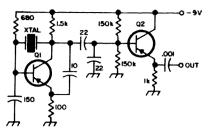

Fig. 44. This untuned crystal oscillator will oscillate with any crystal from 300 kHz to 10 MHz. Frequency stability is very good because the emitter follower buffer amplifier effectively isolates the oscillator from the load. Q1 and Q2 are 2N993, 2N1749, 2N2084, 2N2362, TIM10, GE-9, SK3006 or HEP-2.

connected as an emitter follower. With this arrangement, Q2 acts as a buffer stage and quite effectively isolates the oscillator from the load.

Another untuned crystal oscillator stage is shown in Fig. 45. This circuit will oscillate with any crystal between 3 and 20 MHz with no tuning whatsoever. If overtone crystals are plugged into the circuit, they will oscillate on their fundamental frequency. For overtone crystals up to about 60 MHz, the fundamental will be approximately 1/8 the marked frequency; above 60 MHz the fundamental is normally about 1/8 the marked frequency. For best stability with each of these untuned crystal oscillators, all the capacitors should be high grade silver mica types.

The crystal oscillator shown in Fig. 46 has proven to be extremely stable and easy to adjust. Basically it is a standard Colpitts circuit with the frequency determined by the crystal. By using the appropriate inductors and capacitors, this circuit will oscillate

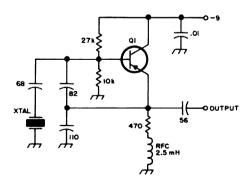

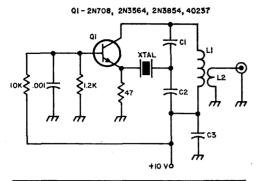

Fig. 45. This crystal oscillator will oscillate with any crystal between 3 and 20 MHz with no tuning whatsoever; overtone crystals will oscillate on their fundamental in this circuit. OI is a 2N1177, 2N1180, 2N1742, GE-9, SK3006 or HEP-2.

Fig. 46. This Colpitts type crystal oscillator may be used with either fundamental or overtone crystals from 10 MHz to 84 MHz with the tuned circuit components listed. It oscillates quite readily when adjusted and provides a stable output.

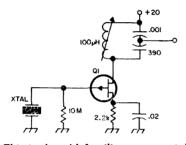

Fig. 47. This is the old familiar vacuum tube Pierce oscillator circuit with a field effect transistor in place of the thermionic triode. Circuit constants shown here are for the I MHz region, but the tuned circuit may be adjusted to any frequency desired. Q1 is a 2N4360 or TIM12.

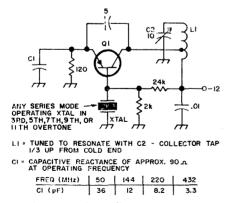

Fig. 48. This crystal oscillator was designed specifically for overtone crystals and will oscillate up to the 11th overtone in the VHF range. Suitable values for CI are shown for the VHF bands; for other frequencies, CI should exhibit approximately 90 ohms capacitive reactance for best results. QI is a TIM10, TI400 or HEP-3.

with either fundamental or overtone crystals. Although circuit values are only provided here up through 84 MHz, this circuit will operate well above 100 MHz with smaller values of capacitance; the only requirement is that they retain a 10 to 1 ratio in capacitance. For operation with a negative supply voltage, ground the 10 volt line shown in the schematic, lift the 1.2k and 47 ohm resistors from ground and tie them to the negative supply. PNP germanium transistors may also be used by reversing the supply voltage and changing the 10K base bias resistor to 33k.

The untuned crystal oscillator in Fig. 47 uses an FET in the familiar Pierce vacuum tube circuit. In this oscillator the drain to source capacitance and gate to source capacitance make up the feedback path with the amount of oscillator excitation determined by their ratio. This circuit cannot be used with conventional junction transistors because their low input impedance severely loads down the crystal.

The crystal oscillator shown in Fig. 48 is designed specifically for overtone crystals and will work up through the eleventh overtone. The circuit is completely noncritical except for the value of C1 which should exhibit approximately 90 ohms capacitive reactance at the operating frequency. The tuned circuit is tuned to the frequency of interest. The 5 pF capacitor from collector to emitter should be adjusted for maximum rf output; above about 200 MHz it may not be required. The constants shown in the schematic should cause oscillation with any overtone crystal in the VHF range, but in some cases a sluggish crystal may require adjustment of the 24k base bias resistor to take off every time power is applied.

Variable crystal oscillator

The variable crystal oscillator shown in Fig. 49 is a very useful circuit to the ham who wants a highly stable signal on two meters or 432. Although it will only tune about 50 kHz on two and 150 kHz on 432, it is adequate for many types of operation. On 432 for example, most operation is within a few kHz of 432.00 MHz. The circuit's operation is quite straight forward; the dual 365 pF capacitor pads down the resonant circuit and pulls the crystal down in frequency. Just how much it is pulled down is determined by the inductor L1. For an

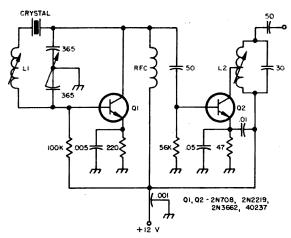

Fig. 49. This variable crystal oscillator (VXO) may be used to vary the frequency of an 8 MHz crystal 4 or 5 kHz when the 365 pF dual variable is tuned through its range. When multiplied to two meters or 432, this provides a very stable variable frequency. For 8 MHz crysals, LI is a 20-25 uH slug tuned coil; L2 is chosen to resonate at 8 MHz with the 30 pF capacitor.

	Table 1	
Crystal	L ₁	L ₂ *
3.5 MHz	35-60 μH Miller 45	509 80 turns #36 tapped at 27 turns
5.0 MHz	24-35 μH Miller 45	508 62 turns #36 tapped at 21 turns
8.0 MHz	16-24 μH Miller 45	507 40 turns #36, tapped at 13 turns
9.0 MHz	16-24 μH Miller 45	507 36 turns #36, tapped at 12 turns

^{*}Wound on ¼" slug tuned form.

8 MHz crystal, this inductor should have a center value of about 22 µH; it should exhibit relatively high Q at 8 MHz and be self resonant well above the crystal frequency. As this inductor is increased beyond a certain amount, the crystal will lose control and the circuit becomes a rather inferior VFO. For best results LI should be adjusted so that the crystal is pulled 4 or 5 kHz when the variable capacitor is tuned through its full range.

The buffer amplifier is coupled to the oscillator through a 50 pF capacitor. For maximum frequency stability, this capacitor should be the minimum value that will provide adequate drive for your transmitter. With the 50 pF capacitor shown, approximately 10 volts of 8 MHz drive should be available with the buffer tank tuned to resonance. Inductor L2 is chosen to resonate at 8 MHz with the 30 pF capacitor; the tap is ½ up from the ground end.

Two frequency crystal oscillator

In the two frequency crystal oscillator illustrated in Fig. 50, the bilateral characteristics of the transistor effectively provide two separate common emitter stages. Either of the two frequencies may be selected by simply applying a positive or negative voltage to the circuit.

When a positive voltage is applied, current flows through D1 to the emitter of the transistor. The tuned circuit consisting of L2, C2 and the crystal Y2 determine the oscillation frequency available at the output. The other tuned circuit consisting of L1 and C1 is shorted out by D1. In addition, since crystal Y1 is connected between the base and emitter, there is no gain to promote oscillation at its frequency.

If a negative voltage is applied to the supply terminal, the transistor "inverts" itself with the collector becoming the emitter and the emitter the collector. In this case L1, C1 and Y1 determine the frequency of oscillation. Diode D2 shorts out the other tuned circuit and the crystal Y2 is connected between the base and emitter of the inverted transistor; therefore, there is no output at Y2's frequency.

Transistors may not normally be used in the inverted mode because rather large

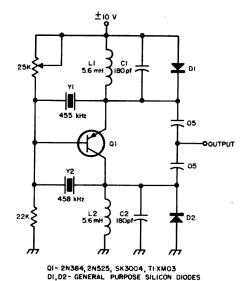

Fig. 50. This two frequency crystal oscillator changes frequency by simply reversing the supply voltage. When the supply voltage is changed, the transistor inverts itself; usually transistors may not be used in the inverted mode, but in an oscillator a gain of only 1 or 2 is needed and this circuit provides a novel and simple way of obtaining two frequencies from a single stage with a minimum of switching.

amounts of gain are desired. However, as an oscillator, the gain need only be sufficient to produce oscillation; this usually requires a forward current gain of only one or two. For this reason almost any germanium transistor may be used in this application. Silicon NPN transistors will also work, but operation will be just opposite to that described above.

Diodes D1 and D2 limit the output voltage to about 0.7 volts, so for some applications, further amplification may be necessary. The tuned circuit values shown in the schematic are for a resonant frequency of 455 kHz, where this circuit provides an excellent method for upper and lower sideband selection. It may be used on other frequencies by simply changing the values of inductance and capacitance in the tuned circuits.

UHF oscillator

The simple UHF oscillator circuit shown in Fig. 51 will deliver up to about 2 mW of power at 1000 MHz. Although this amount of power is insufficient for some applications, 2 mW is more than enough for many mixer and converter circuits. Many transistor types, when selected, will oscillate up to 1500 MHz in this simple circuit.

Ten meter transmitter

The three watt ten meter transmitter shown

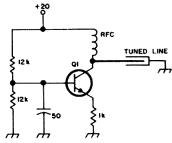

Fig. 51. This simple UHF oscillator will provide about 2 mW up to 1000 MHz; some selected transistors will provide usable power up to 1500 MHz or so. Q1 is a 2N918, 2N3478, 2N3564 or HEP-56.

in Fig. 52 gets over the high rf power/high price hurdle by using three inexpensive transistors in parallel in the final stage. The three paralleled transistors used will produce three watts output with a 15 to 18 volt supply and about 2.25 watts with a 12 volt supply. The rf drive is provided by a 28 MHz crystal oscillator and driver amplifier. For maximum efficiency, modulation is applied to both the final amplifier and driver through the modulation transformer; about 1.5 watts of audio power is required for 100% modulation. Since the transistors used in this transmitter have an fr of 500 MHz, a similar transmitter could be built for six meters; the only change would be in the resonant circuits.

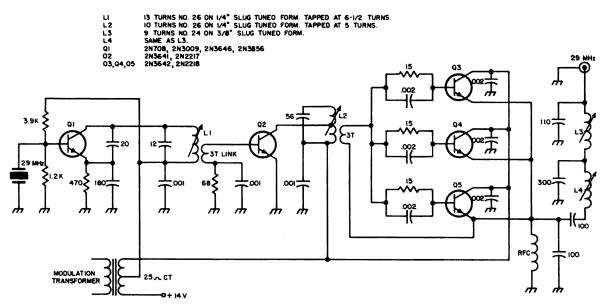

Fig. 52. This three watt ten meter transmitter maintains high efficiency and low cost by paralleling three inexpensive silicon transistors in the final stage.

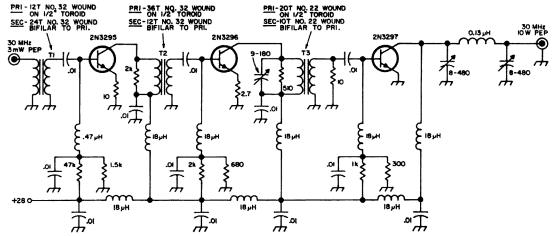

Fig. 53. This ten meter linear amplifier for SSB service uses transistors which were designed specifically for single sideband linear operation. Many junction transistors cannot be used satisfactorily for this application, because linear amplification at low power levels is a serious problem.

Ten meter linear amplifier

Up until the present time transistors haven't been used too much in SSB transmitters because linear amplification at even low signal levels has been a serious problem. However, the transistors in the ten meter SSB power amplifier illustrated in Fig. 53 were designed specifically for linear amplifier service and perform quite well. The measured distortion of these devices is less than three percent without feedback, which is somewhat better than tubes under the same conditions.

Actually the circuit of this amplifier is quite straight forward. The only critical parts are the coupling transformers between succeeding stages. These are wound on small ½" toroids which are suitable for use at 30 MHz (Ami-tron T-50-2). Coupling between stages must be very tight and the

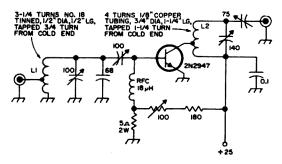

Fig. 54. This ten meter single sideband linear power amplifier will provide up to 8 watts PEP. The power gain of the 2N2947 is 13 dB at this frequency, and the odd order distortion products are at least 30 dB below the desired output.

transformers should be bifilar wound. Both the input and output of this unit are designed for 50 ohm coaxial line, so it fits in nicely with other equipment being used on ten meters.

The ten meter single sideband linear power amplifier shown in Fig. 54 is capable of delivering an output power of 8 watts PEP. The power gain at this frequency is 13 dB, and all odd-order distortion products are at least 30 dB below the desired output.

The main difference between this amplifier and one designed for class C operation in CW, AM or FM transmitters lies primarily in the dc bias circuit. For class C operation, the only dc bias normally applied is the collector supply voltage. The 18 µH rf choke and resistive divider in the base circuit would be omitted. The transistor is biased on by the driving signal on the base. This results in one of the big advantages of the transistor transmitter—if the driving signal is suddenly removed, the power amplifier merely shuts off and sustains no damage.

To obtain linear operation, a small amount of forward bias is applied to the transistor. This is a function of the resistive divider and the isolating choke in the base circuit. The bias is adjusted so that a small collector current flows without any input driving signal; when a driving signal is applied, the transistor is biased on to full operating collector current. In this circuit the 2N2947 draws 20 mA with no drive and 350 mA with full drive.

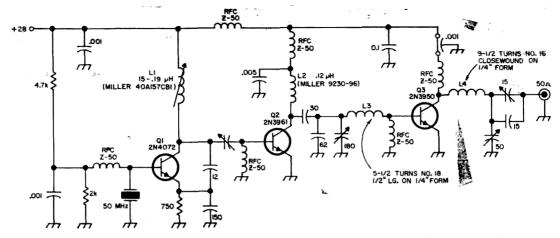

Fig. 55. This 6 meter transmitter provides up to 50 watts of power with very good efficiency and very low harmonics. The 2N3950 in the final provides a minimum power gain of 8 dB on six and is rated at 50 watts continuous service.

Six meter transmitter

The six meter transmitter of Fig. 55 will provide 50 watts of power into the antenna with very good efficiency and very low harmonics. The second harmonic is suppressed on the order of 28 dB while the third harmonic is more than 34 dB down. The efficiency of the final stage is 69% and the overall efficiency of the entire transmitter is 62%. The bulk of the total current drain of 2.9 A is required by the final amplifier -2.6 A. By choosing each of the circuit components very carefully, a transmitter evolved which uses only three transistors where several more stages are normally

required. The mainstay of this transmitter however is the 2N3950 transistor in the power amplifier; this transistor can provide 50 watts of continuous power at 50 MHz with a minimum power gain of 8 dB.

Two meter driver

The simple two meter driver shown in Fig. 56 is just about the minimum that is suitable for driving a small 144 MHz transmitter. The first stage of this VHF driver consists of a crystal controlled oscillator operating at 48 MHz; the 48 MHz output from the oscillator is capacitively coupled to the 2N1141 tripler stage tuned to 144 MHz. The two meter output of this circuit is quite low, but sufficient to drive a small power amplifier to a quarter watt or so. This circuit may also be used as a two meter signal source, or as a source for a VHF SSB mixer.

Circuits for Test Equipment

Signal tracer

The signal tracer is a universally used unit of test equipment which may be used for troubleshooting and isolating defective stages in all types of electronic equipment. With a suitable rf probe it may be used to check the operation of rf and if amplifiers; with an audio pickup probe it may be used as a straight through audio ampli-

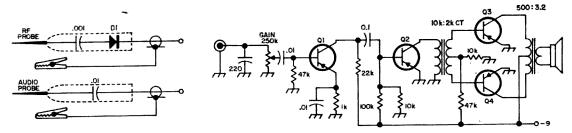

Fig. 57. This signal tracer provides more than adequate audio output with only 100-microvolts of modulated rf at the input. It may also be used for tracing audio circuits, but don't depend on its fidelity. All the transistors are germanium types such as the 2N404, 2N1450, 2N2953, SK3004, GE-2 or HEP-253; the diode in the probe is a IN34A or IN67A or similar.

fier to check microphones and preamps and to detect noise and hum in amplifiers.

The signal tracer shown in Fig. 57 uses a push pull output stage which produces more than adequate audio output to a miniature speaker with only 100 microvolts input. The output from the probe is applied directly to the 250 kilohm pot, which serves as a gain control and as a diode load when an rf probe is being used. The signal is coupled to the base of the first transistor, amplified, and fed to the driver stage and transformer coupled push pull output.

Only a very small amount of audio signal is necessary to operate the signal tracer as a straight through audio amplifier. However, don't use it to check fidelity because it is designed primarily for maximum sensitivity without regard to frequency response.

When using this signal tracer always start with the audio gain control turned all the way down because it is easy to overload the simple amplifier; the result is a highly distorted output signal. In some receivers the rf probe may load the mixer plate or if grid. If this happens, a tone modulated signal should be injected at the antenna terminals of the receiver to obtain a usable output from the signal tracer.

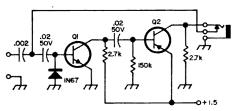

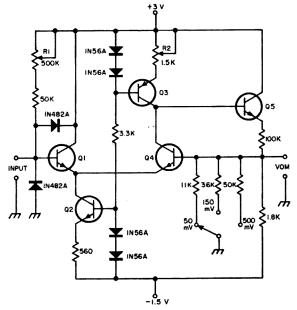

Fig. 58. This signal injector/tracer switches from the injection mode to a signal tracer by simply plugging in a pair of high impedance magnetic earphones. As a tracer is works from audio up to 432 MHz. Transistor Q1 is a 2N170, 2N388A, 2N1605, SK3011 or GE-7; Q2 is a 2N188A, 2N404, 2N2953, SK3004 or HEP-253.

Signal injector/tracer

The circuit illustrated in Fig. 58 functions as both a signal injector and signal tracer. Furthermore, no switching is required; it's all accomplished automatically when the headphones are plugged in for signal tracing. In the inject mode the circuit is a clamped multivibrator with extremely narrow pulses and high harmonic content. In fact, with this circuit, sufficient output is available for signal tracing from audio (750 Hz) to well above 40 MHz. This frequency range is more than adequate for most requirements.

The unit is switched to the signal tracer mode by simply plugging in a pair of high impedance magnetic headphones. In this mode

QI, Q2, Q4, Q5 - 2N13O4, 2N2924, 2N3393, SK3OII O3 - 2N4O4, SK3OO3, SK3OO4

Fig. 59. This VOM range extender increases the sensitivity of your volt-ohm-milliammeter to 50 millivolts full scale; full scale readings of 150 and 500 millivolts are also provided by the range switch.

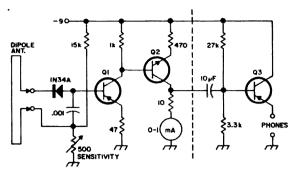

Fig. 60. This monitor/detector may be used for measuring field strength, monitoring modulation or finding hidden transmitters by simply attaching a resonant dipole antenna at the input. Q1 and Q3 are 2N408, 2N2953, SK3004, GE-2 or HEP-253; Q2 is a 2N170, 2N388A, 2N1605, SK3011 or GE-7.

it will detect and amplify signals from 20 Hz to above 432 MHz. Since this circuit only requires about 100 microamperes, no on-off switch is provided. This very small current drain insures that the life of the battery will be nearly that of its shelf life. By using miniature components and a little care in layout, it is possible to mount this complete injector/tracer in an old penlight case or metal cigar tube.

VOM range extender

Most volt-ohm-milliammeters are not too suitable for use with transistor circuits because their lowest voltage scales are either 1.5 or 3 volts full scale and they are not sensitive enough to accurately measure the base to emitter voltage of a transistor which may be 120 millivolts or so. The low voltage dc preamplifier shown in Fig. 59 is inexpensive, stable with temperature and supply voltage variations yet extends the range of any VOM so it can be used effectively in semiconductor circuit measurements.

In this circuit transistors Q1 and Q4 constitute an emitter coupled amplifier; Q5 is an emitter follower connected so the circuit's entire output voltage is fed back to Q4. Transistors Q2 and Q3 are constant current sources in the negative and positive lines respectively. These constant current sources reduce the sensitivity of the amplifier to voltage supply variations and result in substantially lower drift. To control the gain of the amplifier for different voltage ranges, a portion of the output voltage is fed back to the base of transistor Q4 through the voltage divider selected by the

range switch. With the values shown in the schematic, this circuit provides gains of 3, 10 and 30, which extend the 1.5 volt scale of the VOM to 500, 150 and 50 millivolts full scale.

There are two zero controls which must be adjusted when using this unit; first the 500 kilohm pot (R1) in the base bias lead to transistor Q1 is adjusted to zero the output with no input and the base isolated from ground. The 1.5k zero adjust pot (R2) is then adjusted for an output zero with the input leads shorted together.

Monitor/detector

The simple VHF monitor/detector illustrated in Fig. 60 may be used for measuring field strength, monitoring modulation or even in hidden transmitter hunts. The frequency of use may be simply changed by changing the length of the dipole antenna. In some cases where the rf field is strong enough, a simple vertical pickup antenna will be sufficient for signal monitoring purposes. Furthermore, the use of this monitor/detector is not limited to the VHF bands; the addition of an appropriate antenna will permit its use at any frequency up to about 500 MHz. For lower frequencies where the size of the dipole antenna would be impractical, a simple vertical pickup antenna and tuned resonant circuit may be substituted at the input.

1 kHz oscillator

The simple 1 kHz oscillator shown in Fig. 61 is very useful for many testing devices around the shop. This circuit is simply a Colpitts oscillator, but the circuit values and feedback have been chosen for maxi-

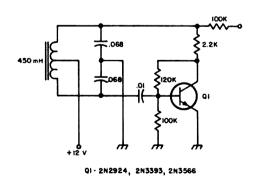

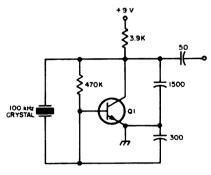

Fig. 61. Simple 1000 Hz oscillator is very useful for testing and measurement around the shack. The Colpitts circuit is used with component values chosen for maximum stability and good waveform.

Q1 - 2N7Q9, 2N2711, 2N2923, 2N3691

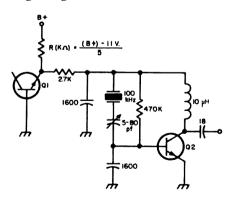

Fig. 62. The 100 kHz calibrator shown here is just about the simplest circuit that will provide usable results. For zeroing in with WWV a small padder capacitor may be added in series with the 100 kHz crystal.

mum stability along with good waveform. It may be used for testing speech and modulation equipment, or even as a driver for a code practice oscillator.

100 kHz crystal calibrators

The 100 kHz crystal oscillator illustrated in Fig. 62 is just about as simple as you can build and still get a usable output. This circuit will provide usable harmonics up to about 30 MHz but it has no provision for zeroing in with WWV. This feature may be added by simply placing a small variable padder capacitor in series with the 100 kHz crystal.

The calibrator circuit shown in Fig. 63 is only slightly more complicated than its counterpart in Fig. 62, but provides usable harmonics up to 150 MHz and has a built in voltage regulator. In this case the base

QI ANY NPN PLANAR SILICON TRANSISTOR Q2 2N2925, 2N3392, 2N3565, SE4002

Fig. 63. This 100 kHz crystal calibrator is only slightly more complicated than the one shown in Fig. 62, but has a built in voltage regulator (QI) and provides usable harmonics up to 150 MHz.

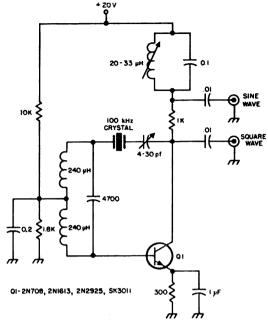

Fig. 64. This 100 kHz crystal calibrator uses a crystal in the parallel mode and provides either a sinusoidal or square wave output. The calibrator may be zeroed to WWV with the 4-30 pF trimmer.

to emitter junction of an NPN silicon planar transistor is connected as a zener diode. When connected in this manner, these transistors provide a regulated voltage of approximately 11 volts. The value of the series dropping resistor may be determined by using the formula shown in the schematic. The 5–80 pF capacitor is for zeroing in with WWV.

The 100 kHz crystal controlled oscillator shown in Fig. 64 uses a low cost silicon transistor, and provides both a square wave and sine wave output with excellent frequency stability. The oscillator circuit is basically the Hartley type with positive feedback from the collector to base through a phase reversal in the tapped tank circuit, consisting of two 240 µH chokes and a 4700 pF silver mica capacitor. The oscillator frequency is determined by the resonant frequency of the very high Q series LC network in the feedback loop. This network is made up of the 4-30 pF variable capacitor and quartz crystal which operates in the parallel mode. The variable capacitor provides a fine frequency adjustment control. Feedback is sufficiently large to assure normal circuit operation almost completely independent of transistor gain. The large amount of feedback drives the collector from cutoff to saturation, making a square

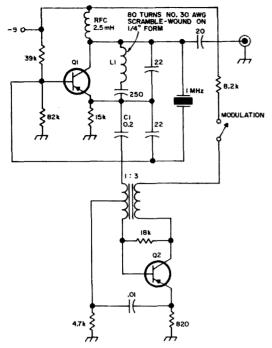

Fig. 65. This crystal controlled oscillator provides very distinctive markers up to 30 MHz. The modulation frequency is approximately 1000 Hz, but by changing the value of C1 it may be changed slightly. Q1 is a 2N384, 2N1742, 2N2362, 2N2084, TIM10, GE-9 or HEP-2; Q2 is a 2N2613, 2N2953, 2N1303, SK3004, GE-2 or HEP-254.

wave available at the output. A sine wave is developed across a tunable high Q tank and is also available at the output.

Modulated band edge marker

The crystal controlled calibration oscillator shown in Fig. 65 is especially useful for band edge marking and providing distinctive crystal controlled markers up to 30 MHz. To assist in identification of the marker, particularly at the higher frequencies where the harmonics are quite weak, the note may be modulated by simply turning on the audio oscillator. The modulation frequency of this unit is about 1000 Hz, but it may be changed slightly by changing the value of C1. If the oscillator fails to oscillate when power is applied, reverse the connections on one side of the transformer. At the lower frequencies the output of the calibrator may be coupled into the antenna circuit of the receiver by inductive coupling, but on 15 and 10 meters, a direct connection to the antenna terminals may be necessary to obtain sufficient output. Although this circuit is designed for a one MHz crystal, other crystal frequencies may be accommodated by changing the number of turns in LI.

The two meter band edge marker illustrated in Fig. 66 provides very strong harmonics of an 18 or 24 MHz crystal on 144 MHz; when a sensitive converter is used on 432, harmonics may also be heard on this band. This circuit will oscillate with crystals throughout the 18 to 24 MHz region, so it may be used as a marker at almost any VHF frequency. The use of a 20 MHz crystal for example would be very useful for marking the lower edge of the amateur 220 and 420 MHz bands. If a modulated marker is desired, the audio oscillator (Q2) of Fig. 65 may be coupled into the base of the oscillator through a 0.2 µF capacitor.

Sweep frequency generator

More and more hams are finding out that the sweep generator is one of the most useful test instruments to have around the shack. It may be used to align communications receivers, VHF converters, to plot response curves and to check bandwidth. The circuit illustrated in Fig. 67 is a very simple unit that may be used at any spot frequency between 100 kHz and 60 MHz. Although a three range bandswitch is shown in the drawing, it may be omitted if only one spot frequency is required (455 kHz for example).

The sweep generator shown here consists of a single unijunction transistor sawtooth generator which provides the sweeping signal for the oscilloscope and the fixed tuned rf oscillator. The output of the sawtooth generator is connected across a 56 pF varicap in the oscillator tank which varies the frequency of the oscillator in step with the scope trace. The sweeping frequency may

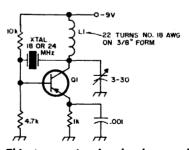

Fig. 66. This two meter band edge marker provides useful harmonics up to several hundred MHz with 18 or 24 MHz crystals. If modulation is desired, the audio oscillator from the circuit of Fig. 65 may be coupled into the base. Q1 is a 2N1745, 2N2362, or HEP-2.

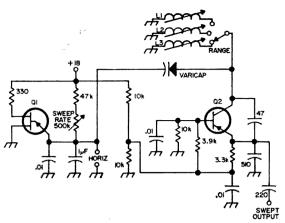

Fig. 67. A sweep frequency generator is a very handy gadget, but many times the commercial units are more complicated than the ham requires. This simple sweeper may be used at any spot frequency between 100 kHz and 60 MHz by simply using the coils listed in Table 2. By using a three position range switch, the three most popular frequencies may be used, such as 455 kHz, 1600 kHz and 10.7 MHz. QI is a 2N1671, 2N2160, 2N2646, 2N3480. or HEP-310; Q2 is a 2N741, 2N1747, 2N2188, GE-9 or HEP-2. The varicap is a 56 pF capacitance diode such as the 1N955 or TRW V56.

be varied between 5 and 30 sweeps per second with the 500k sweep rate control.

The center frequency of the swept output is determined by the coils that are connected across the range switch. A listing of coils for all frequencies from 65 kHz to 60 MHz is listed in Table 2. When using this generator, always use the slowest sweep speed that will provide a usable trace on your oscilloscope. The slower the sweep speed, the more accurate the reproduction of the response curve; if the generator is swept at too fast a rate, the resonant circuit being swept may ring and distort the curve.

Sawtooth generator

Sawtooth generators are very useful in many measurements and their circuitry may be greatly simplified by the use of field effect transistors. When conventional junction transistors are used for this purpose, complex feedback networks and methods of compensation must be used to generate a linear voltage ramp. The output waveform of the sawtooth generator shown in Fig. 68 is linear within 2% and may be adjusted from 1 kHz to 3 kHz by the center frequency control. The thermistor R1 provides temperature stability and circuit loading is reduced by the use of a source follower at the output.

Square wave generator

The square waves available from most inexpensive signal generators deteriorate pretty badly at the higher frequencies. In

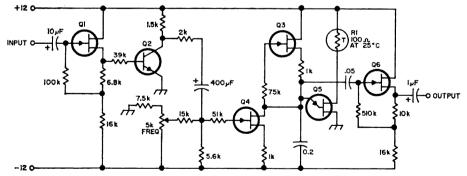

Fig. 68. This simple sawtooth generator is linear within 2% and may be adjusted from 1 kHz to 3 kHz with the center frequency control. Q1, Q3, Q4 and Q6 are FET's such as the 2N3819, 2N3820, TIS34, MPF105 or HEP 801; Q2 is a 2N388, 2N2926, 2N3391, SK3011 or HEP-54; Q5 is a 2N1671, 2N2160, 2N2646, 2N3480 or HEP-310.

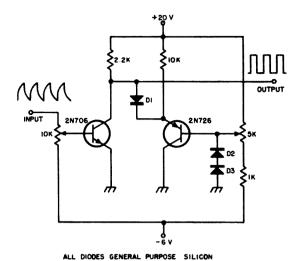

Fig. 69. The square wave output of many inexpensive signal generators deteriorates guite badly at high frequencies, but this circuit will square them off again. The diodes may be any inexpensive computer type such as the IN914.

addition, the output amplitude often varies with frequency. The addition of the simple circuit illustrated in Fig. 69 to the output of the signal generator will provide a good square wave output with an amplitude that does not vary with frequency.

In this circuit, Q1 is an inverter, while Q2 and the 5 kilohm amplitude control pot provide a variable clamp voltage for the output. In most cases, the necessary positive and negative voltages may be obtained from the signal generator's internal supply. The input potentiometer should be adjusted for best output waveform. Once this control is set, it will not change unless the signal generator varies significantly. Ideally, this control should be adjusted so that the input signal provides a voltage swing at the base of Q1 from +3 to -5 volts. The silicon diode D1 provides protection for the emitterbase junction of Q2. Diodes D2 and D3 prevent the clamp voltage from reverse biasing Q1.

Capacitance meter

The direct reading capacitance meter illustrated in Fig. 70 has four direct reading capacitance ranges from zero to 0.1 µF. Although electrolytic capacitors cannot be measured with this circuit, any type of nonelectrolytic capacitor may be checked. In fact, it works as well with variable capacitors as with fixed; the meter deflection will follow the capacitance change as it is tuned. The four direct reading ranges are 0-200 pF, 0-1000 pF, 0-0.01 µF and 0-0.1 μF. The lowest capacitance which may be accurately read is 4 pF, but 2 pF may be estimated quite easily.

In this circuit transistors Q1 and Q2 are connected in a conventional free running multivibrator. The output from the collector of Q2 is a constant amplitude square wave whose frequency is determined by the values of the resistors and capacitors connected across the base circuit of Q1 and Q2. The square wave output from the collector of Q2 is coupled through the unknown capacitor connected across the test terminals to the metering circuit consisting of the 1N34A diode, the potentiometers and the de microammeter. For any given square wave frequency, the deflection of the meter will be directly proportional to the capacitance across the test terminals. For example, if a precision 100 pF capacitor is connected across the test terminals and the calibration pot is set for full scale deflection, the

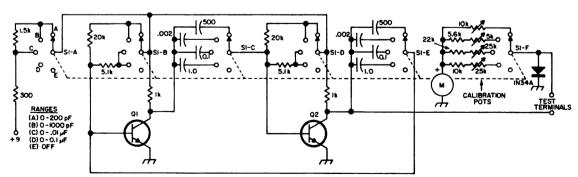

Fig. 70. Although this capacitance meter will not measure electrolytic capacitors, it will measure any other type from zero to 0.1 μF with reasonable accuracy. On the lower end 4 pF can be read accurately and 2 pF easily estimated. Transistors QI and Q2 are 2N168, 2N1605, 2N2926, SK3011 or HEP-54; the meter is a 0-50 microampere unit and the range switch a Centralab PA1021.

meter will have a range from zero to 100 pF. The response of this circuit is essentially linear, so 50 pF would provide half-scale deflection, ½0 scale deflection would indicate 10 pf, etcetera. To change the range, the frequency of the multivibrator is changed by choosing new values of resistance and capacitance in the base circuits of Q1 and Q2.

Calibration of the direct reading capacitance meter requires the use of four accurately known capacitors—0.1 μ F, 0.01 μ F, 1000 pF and 200 pF. These capacitors should be very carefully chosen because the accuracy of the completed meter depends on the tolerance of the calibration capacitors. In addition, it is essential that they are not leaky; if they are, the calibration will not be accurate. To calibrate the meter, set the range switch in the appropriate position, connect the respective calibrating capacitor across the test terminals, and adjust the calibrating potentiometer for full scale deflection of the meter.

Although electrolytic capacitors cannot be measured on this instrument, it will check all other types. If a capacitor is open, there will be no deflection on any range. If it is leaky or shorted, the meter will deflect below zero. It is imperative that leaky and shorted capacitors be immediately disconnected from the test terminals to prevent damage to the diode and microammeter.

High impedance scope probe

Most oscilloscope probes are unsuitable for use with high impedance circuits because they severely load them down. By using the high input impedance characteristics of the field effect transistor, an extremely high impedance probe may be produced. The circuit shown in Fig. 71 uses

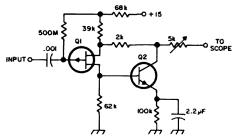

Fig. 71. This high impedance probe provides about 1200 megohms input impedance with unity gain. Upper frequency equalization is provided by the 5K pot. Q1 is a U112, 2N2607, 2N4360 or TIM12; Q2 is a 2N706, 2N708, 2N2926, 2N3394, or HEP-50.

the bootstrap action of the 500 megohm resistor to raise the input impedance of the circuit to 1200 megohms. The 2 kilohm feedback resistor from the collector of Q2 maintains unity gain while the 5k potentiometer provides circuit equalization. The rise time of this circuit is extremely fast, typically less than half a microsecond. In addition, it can handle up to two volt signals (peak to peak) without distortion.

Microammeter amplifier

The sensitive microammeter amplifier illustrated in Fig. 72 may be adjusted from approximately 2 μ A to 100 μ A full scale deflection each side of zero. The input impedance of this circuit is 60 kilohms at 2 μ A sensitivity and 2.5 kilohms at 100 μ A sensitivity; total battery drain is 1.5 mA.

In this circuit a differential amplifier with degenerative biasing and collector meter feed provide a satisfactory compromise between sensitivity and stability. The transistors used in this circuit should be chosen for high current gain throughout the emitter current range; in addition, they should exhibit very low leakage currents. The 50 ohm null potentiometer is used to compensate for any differences in the base-emitter voltage of the two transistors. The balance pot is used to compensate for dif-

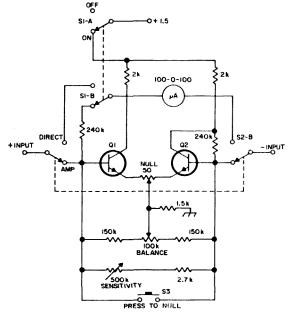

Fig. 72. This very sensitive microammeter amplifier may be adjusted from 2 μ A to 100 μ A each side of zero; the input impedance varies from 60K at 2 μ A to 2.5K at 100 μ A. Transistors Q1 and Q2 are 2N930, GE-10 or HEP-50.

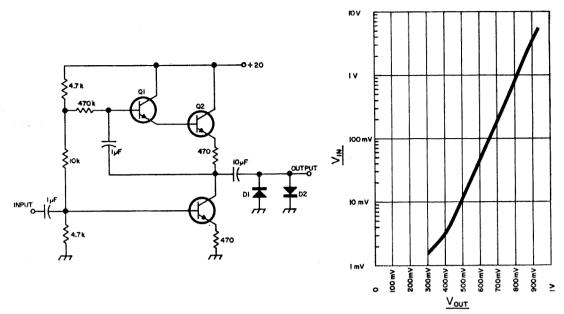

Fig. 73. This logarithmic amplifier makes use of the fact that when two back to back diodes are driven by a current generator, they exhibit a logarithmic output of the input signal. With the circuit constants shown, this amplifier follows a nearly perfect logarithmic curve over a 60 dB range; selected diodes will increase this to 80 dB. Q1, Q2 and Q3 are 2N2924, SK3019, GE-10 or HEP-54; D1 and D2 are 1N914.

ferences in components and transistor current gain.

The null adjustment is made with S3 depressed, S1 on and S2 on "amplifier." The balance is adjusted with S1 on and S2 on "direct." Although the null is completely independent of the balance adjustment, the balance must be changed each time the null is changed. For improved sensitivity a 50-0-50 μ A meter may be used instead of the 100 μ A movement, but at the cost of reduced stability.

Logarithmic amplifier

Logarithmic amplifiers are very useful for making measurements that require very large changes in input voltage or current. The 60 dB logarithmic amplifier shown in Fig. 73 makes use of the fact that when two diodes are driven by a current generator, they exhibit a logarithmic output of the input signal. Two 1N914 diodes were

chosen for this amplifier because they follow an almost perfect logarithmic curve over a 60 dB range; by selecting diodes, it is possible to obtain the same type of curve over an 80 dB spread.

To insure that load changes are not affected by Q1, its output impedance must be extremely high; to cover the 60 dB range for example, the impedance must exceed 100 kilohms. This is accomplished by the Darlington pair, Q1 and Q2 and the 470 ohm resistor in the emitter of Q2. If Q3 is maintained in its linear range, its ac collector current is completely independent of the collector load. Hence, it presents a very high output impedance to the diodes; greater than 100,000 ohms with almost any silicon planar transistor. The input impedance of this circuit is approximately 2000 ohms, so it may be driven from a variety of sources.

The Importance of Being Grounded

Ground paths and ground connections are important at all frequencies from dc on up. As the frequency increases, however, the ground path becomes trickier and harder to predict. When time is spent making any ground path neat, direct and predictable, a potentially serious source of trouble in the circuit is eliminated.

Have you ever had rf all over the shack or a power amplifier or if strip just not act right? The trouble could be lack of a secure, solid, short rf return path to the cathode or emitter of the stage. An example of the need for a good return path is probably a few feet away as you read this. Notice the cord to the lamp you are probably reading by. It contains two wires, one to supply current to the lamp, and the other to allow the current to return thru the transformer. Notice (or be informed!) that both wires are the same size, correctly inferring that both are of equal importance. Remove one of the wires and no light! So watch your grounds and regard them as equal in importance with the coils, capacitors and other components of your rf cir-

An unpredictable ground on a power amplifier can produce rf all over the shack. To see why, let's remind ourselves of a few things about radio frequency energy. rf current always takes the path of least resistance and inductance. If a less inductive route exists around a long path than thru a shorter path broken by a bolted joint or partition, then the current will go the long way. Partitions are harmful to the return path because when they are tight, rf curents cannot go around them, nor can they penetrate thru to the other side. A phenomenon called skin effect causes rf currents to run only along the surface of a conductor, penetrating less than 10 mils at even the lowest amateur frequency in aluminum, even less in copper.

Additional things to remember are that bolted joints are always lossier than a straight plate, and rf energy does not like to go around sharp corners or around edges of material to get where it's going.

The way some power amplifiers are built, it's a wonder that they are as stable or as interference free as they are. Imagine the rf return current from a high power amplifier having to sneak along the chassis, once it leaves the output connector, going under partitions and across bolted joints to get back to the PA cathode. More than a bare minimum of it is going to go around, travelling along the outer surface of the rig. When this happens, the chassis radiates and sometimes develops an appreciable difference of potential from surrounding and perhaps better grounded metallic objects. Presto—a rig that produces rf in the shack.

What does one do about all of this? Simply provide a neat, direct and predictable ground for the stage. A flat piece of copper or other conductor run directly from the output connector to the cathode is best, a heavy wire can be used to get by on.

If no reasonably thin copper strap is available a favorite (and enjoyable) stunt is to cut a beer can at the seam (must be emptied first) and scrape away the lining where it is desired to solder. The half quart size is (smack) best. Aluminum is less satisfactory to use as all connections are normally only bolted down and a connection to the tube base and the cathode pin directly from the nearest point of the strip is not easy to obtain.

The rf current will flow along one side of this strip as the edge tends to restrict current flow to the surface upon which it was launched. When tying components to the strip, use the same side for best results, particularly at the higher amateur frequencies.

To complete the job, tie all bypasses and tuning capacitors directly to the strip, or run a large lead directly to them. Don't depend on a shaft bushing to provide the return path for these critical rf components as this path may be longer than the one discussed earlier that went from the output connector to the cathode. Most components that are adjusted in operating the gear end up bolted thru the front panel and really deserve a much better return path to the cathode than they usually end up with.

As the frequency of operation increases, the effects discussed will become more pronounced. Currents will travel ever closer to the surface and direct ground paths will become more important. They are already important at even the lowest amateur frequency.

Let's review the important points now that the groundwork (!) has been laid:

- 1. Use a neat, direct, predictable ground plate from output or load back to the cathode.
 - 2. Avoid bolted joints in the return path.
 - 3. Avoid going under tight partitions.
- 4. Tie all bypasses and tuning capacitor frames back to the ground plate. Remember that:
- 1. rf currents do not penetrate very deep but flow along the surface of a conductor.
 - 2. rf currents will not go thru a plate.
- 3. rf curents tend to stay on the suface upon which they are launched.

rf power amplifiers are not the only things that require good ground returns. That has been the main topic here, but the ideas are 100% applicable when constructing stable drivers, oscillators, rf and *if* amplifiers, and even audio amplifiers. They all deserve the same treatment: a neat, direct and predictable cathode return path.

The essential thought here is that the builder of any piece of gear should sit down and trace out the ground return path

of every stage. Where a direct path from one cathode or emitter to the next is not obvious, continuous and relatively unimpeded—put it in yourself.

The results can be quite dramatic. A thousand watt class C amplifier that was recently designed and put into service here at WA6KLL was constructed using a 3" wide copper strip down the front panel and directly back to the cathodes of the two 813's. All bypasses from the tube socket were tied directly to this strip. The output connector and the tuning capacitors all mount thru the strip and the front panel and are strapped to the strip. The shielding to the compartment consists of aluminum screen with the frame secured by catches spaced at a quite wide 7 inch interval. There is no radiation of energy from the cabinet even with this minimal shielding. A portable TV ten feet away using an indoor antenna in our fringe area is unaffected when the transmitter is keyed, even on channel 2 (50 miles over hills). The ground return may not be the whole answer, but nobody's touching it!

The problem with specifying good return paths on circuits is that the schematic remains the same. If you are homebrewing from someone else's schematic, you had better know at least as much about the ground return problem as the designer or problems may occur. It is the rare construction article that delves far enough into fundamental" "well-known, concepts grounding. Usually the requirement for considering the returns is your responsibility as the builder. Failure to consider the ground path (since it is not particularly specified on most schematics) may be the cause of a perfect circuit that just doesn't work well for some reason.

If you ever have any doubt about the path return currents must take in any stage, provide one yourself that you can depend on. The results will often be well worth the trouble.

Gus: Part 21

The trip to Mombasa was very enjoyable, plenty of good food and plenty of good rest. No/MM this time, the ship had a new wireless operator who knew nothing about ham radio, plus the fact he was new on the job and did not want to "take a chance", even tho I were willing and ready to get going from the ship. The rest did me plenty of good and I had time to get all my logs ready to be mailed to Ack upon my arrival in Mombasa. Good old Leny 5Z4GT and 5Z4AA met me at the docks when the ship arrived. 5Z4AA was way up in the Police Dept. and a nod from him to Customs did the trick. and in a few moments all my equipment was in Leny's car and away to my hotel we went. I spent only one or two days in Mombasa, did a little shopping down at the local market place—where all those carvings are-REMEMBER! I had nothing to trade them this time so I had to do it the hard way-by bargaining a few hours, even though I spent only about maybe \$10.00 I got a big armfull of some FB carvings. I had found out how to "bargain" with these people while "drinking their Cokes", and I still think they love it. A few even remembered me being there before-One referred to me as that big business man from America. They never say the U.S.A.-You know they call us Americans, this is true in every country I have ever visited. Not just Kenya. They were referring to my big business deal" that I had with them a few years previously when I traded all that "genuine

plastic" jewelry to them. THEY WANTED TO KNOW DID I BRING SOME MORE!!! They all thought I was a "Big Deal" fellow.

The evening's train was caught for Nairobi, you know it only makes that trip at night, I guess it's too hot to be made in the daytime, plus the fact at night they sell you a "sleeper coach ticket" and that puts a few more pounds in someone's pocket I suppose. Arriving back in Nairobi was sort of like coming back home, all the sights was familiar to me, even the taxi drivers with those LONG earlobes with the hole in them and the tall, Fez-sort-of-looking hats they wear. Good old George 5Z4AO met me at the train and away to his home we went, outside the city limits of Nairobi a few miles. Right besides hole Nr. 5 of a golf course which had that sign near hole Nr. 5, saying, "beware of the lions near hole 5". And don't think this sign is there just to be funny-there are LIONS around there, George said one night he saw five of them walking across his lawn. There are also hyenas there, George put a piece of meat on his front steps one night and about midnight there was that laughing hyena sound out on the FRONT PORCH, and there they were fighting over that chunk of meat. George at that time was working with Kenya Television near Nairobi and he had the usual "understudy" following him all over the place when he was on the job. His

MEAT AND POTATOES AND SOMETHING CALLED VALUE

I am always on the lookout for electronic components or assemblies which possess potential ham value. I have also been interested in any item which makes it possible for more hams to enjoy sideband. You can, therefore, understand how happy I was when on a recent western trip I found one lot of 225 watt core power transformers and in another area a batch of computer grade electrolytic condensers. Immediately, I felt that we could put out a darned good universal transceiver power supply and when I got back, the boys in the shop confirmed this.

I say universal because with two of these power transformers and two 500 mil chokes, 12 diodes, assorted resistors and other components, we were able to make up a supply which met the requirements of the latest Swan, Collins, Drake, Hallicrafters, Heath, and National transceivers. Talk about value! We can offer this complete assortment of parts including a 16 gauge steel chassis and bottom plate, a good PM speaker and mating plugs for your particular transceiver for just \$50. The transformers in this set weigh 17 lbs. and altogether the completed supply will weigh close to 40 lbs. This is what I call meat and potatoes. The filtering is excellent; the regulation is extremely good, and we have schematics and a printed story to be supplied with each kit, giving detailed infor-

mation as to how to make the connections for your rig. You will have to tell us what model vou own.

This is what the power supply will do: 800-1000 V at up to 400 mils on peak 285-320 V at up to 300 mils bias of up to 125V at 100 mils 12V DC at 1 ampere 12.6V AC at 6.5 amps Remember, this is an assembly of parts.

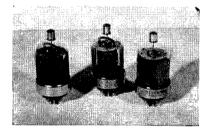

We do not furnish a drilled chassis; we do not furnish the hardware; we do not furnish the solder and the wire but literally everything else is supplied.

Please allow for 45 lbs. shipping weight or otherwise be prepared to accept Railway Express or motor truck shipment.

AMERICAN BEAUTY 3138 100 watt SOLDERING IRON - \$4.95

This famous iron has been standard in our trade for over 25 years. It will operate year in and year out without failure for it is built like the proverbial battleship. Especially well balanced for heavy use. Heavy enough to solder to a chassis and light enough for all general work. The soldering tip is iron plated which greatly reduces pitting and redressing and saves you time if you work with an iron all day long. The casing and body are of one-piece seamless steel. The shatter-proof wooden handle is coated with a durable rubberoid for personal handling comfort. Has a cooling baffle; uses an extra-flexible cord which with stands repeated kinking, and bending. Supplied with tip and stand. One of the most useful and best values I have ever offered. Absolutely new. \$12.50 value—my net is \$4.95. Allow postage for $2\frac{1}{2}$ lbs. Only 275 available.

6146B/8298A by SYLVANIA only \$4.50 each

The latest, freshest, most durable, and highest-rated 6146 ever made is offered this month at a special price of but \$4.50 each. Compare quality and price; then order 2 or more as spares. Absolutely new—and guaranteed, of course. Allow ½ ib. postage per tube.

Telephone 617-456-3548

understudy I think he said was "Kyuku," one of the natives of Kenya. George suddenly has left 5Z4 land you know for ZS6 land so I guess that 5Z4 fellow has stepped into his job. Boy I bet that Nairobi T.V. is not on the air 100% of the time. I guess being from ZS land (that's where George is from you know) is sort of tough on a fellow in 5Z4 land. Must be getting sort of tough all around now because Leny 5Z4GT, I understand will be leaving, I think next year for U.K. Sort of looks like all of them are leaving. Robbie is still there, had a QSO with Wayne Green W2NSD/1 from 5Z4ERR a few weeks ago. I wonder if he will be leaving one of these days? Maybe the day will come when 5Z4 will become a rare one? Maybe someone will have to go there to give the boys a new one some time. George told told me ALL ABOUT the situation when I were there, a very interesting story too. Time to depart for Ruanda and Burundi soon arrived and George took me down to catch the train. George's wife is incidently a good cook, fellows, hunt them up if you happen to get down to ZS6 land sometime. Tell em, "Gus sent me".

The trip to Lake Victoria was only a few hours, I saw the "Great Rift Valley" from the train. In fact the train goes thru the Rift Valley, a sunken portion of the country quite a number of miles across in this portion of Africa. I understand this Rift Valley extends from down near Northern Rhodesia all the way up thru Africa, across Asia Minor across Iran maybe even into Russia. Maybe part of it is in Eastern Turkey where they had the big earthquake a little while back. It could be seen very easily from the train. The land had sunken down some hundreds of feet I would estimate.

Arriving in Kismu on Lake Victoria the weather was extremely hot. Loading the Lake steamer took about four hours it seemed to me. The boat was full mostly of natives, some returning to their homes from working in Nairobi or maybe Nakuru or maybe even Mombasa. Quite a number of Europeans in their White suits also went on board. The steamer headed across the lake for Kampala, Ugunda. Taking about one half the day to get there. The ship was close to the land quite a while and many crocodiles were seen, even a few hippos and even some dozen or so wild water buffalosthats those "mean ones" that you don't monkey around with at all. Those are the ones you had better "kill" if you shoot at them or you are in for a lots of trouble. I was glad we were on a ship and they some distance away, even then they gave the boat a "mean look". The crocodiles just sank below the water and disappeared from sight. Upon landing in Kampala everyone went ashore and we were taken to a nearby water-front hotel and told to have a drink on the house, some of us wandered out and walked around town. I picked up a few carvings and some native-made items. The weather was too hot for me to walk all over so I headed back to the hotel/restaurant. Stayed there some three or four more hours until we were told to go back to the ship. The little whistle tooted a few times and we were away for the Sourthern part of Lake Victoria. The ship docked at Mwanza which is in Tanganyaki. This was where I was to meet 9U5JH from Ruanda. He was to arrive late that afternoon. I was met at the docks by a VQ3 fellow from either Kanama or Shinyanga where he was managing a diamond or gold mine. He was originally from ZS land so I am quite sure he is not in Tanganyake at this time. He drove me in his car all over the little town and we had a very fine meal at a local hotel-restaurant and chatted until late in the afternoon when John, 9U5JH arrived in his 1959 Chevrolet which he had driven all the way from Burunda. All three of us had a big "eye ball QSO" for an hour or two, the VQ3 chap departed for his home QTH, John gassed up filling a few five gallon cans full of gasoline for the trip back to Burunda across unchartered roads with no filling stations and no signs of civilization at all were seen by us as we drove to 9U5 land that night. All THREE SPARE tires was carefully checked, two spare cans of water was filled, a few extra quarts of oil were bought, and away for 9U5-Burunda we went. Now don't get the idea that there is an "interstate highway between these two places, don't get the idea that it's even a paved road, or you will be completely wrong. This auto trip was nearly what you might call a safari. We were packed for a safari I would say. We had everything a safari has except "guns". Later on I sure wish we had a gun or two with us. This was going to be another of those trips I was to remember all my days. Dirt roads all the way, not one single road sign and many many roads turning off to the right and left. All of them

102 73 MAGAZINE

looking right to me. A few times we chose the road by refering to our compass. OH YES we took quite a few wrong roads. John could speak Swahili so we had no trouble getting back on the right road, but if you don't speak Swahili-Brother don't vou dare make this trip or you will end up staying there all the rest of your life. No one we met all the way spoke ONE WORD OF ENGLISH, and Brother this can get rough. Most of the natives were more or less friendly, but a number of them looked downright "mean" to me, not a sign of a smile could be seen on their faces. When you leave the town limits of Mwanza and are out on that road a few hours, you know you are in "deep Africa", you smell it, you see it, you hear it, you hear in the distance the beating drums (this trip was an all night affair you know), even the stars sort of have that African look, the trees are a dead give away. You remember seeing those "flat top" trees in African movies? Well they are here, and I mean all over the place. Those darn beating drums are what got to me more than anything else, some sounded like they were saying bong, bong, bong diddy bong, others sounded like bang, bang space bang bang bang, All had a different sound and were beat in a different sounding way. I was thinking to myself something like this-"I wonder what those things are saying to each other". Because some of them were most certainly answering the other drummer's CQ. I wonder when they sign off do they have a certain thing that says 73? Those jungle sounds were sometimes frightening, at times smooth, and sort of soothing. I had been in the African jungle before a number of times between Mombasa and Nairobi, Kenva and twice between Nairobi and Dar es Salaam, Tanganyaki, but I was in a bus along with about 25 or so people all the time and on at least a 'marked road". You might say the other roads were roads that were traveled on by a good number of cars every day. But this was now a real "back country" road and lead us straight in the middle of real wild country-a part incidently where Dr. Livingston went for supplies to Dar es Salaam and very definitely a portion was used by Stanley when he was hunting Dr. Livingston. This was an all night trip and half of the next day. You know wild animals are daytime sleepers and roam around at night. So doggoned many different kinds of ani-

SUB-MINIATURE SOLID STATE TV CAMERA

FOR CLOSED CIRCUIT OR AMATEUR TV

THE VANGUARD 501 is a completely automatic closed circuit television camera capable of transmitting sharp, clear, live pictures to one or more TV sets of your choice via a low-cost antenna cable (RG-59U) up to a distance of 1000 ft without the need for accessories or modifications on the TV sets. The range can be extended indefinitely by using line amplifiers at repeated intervals or by using radio transmitters where regulations permit.

There are hundreds of practical uses in business, home, school, etc. for any purpose that requires you or anyone chosen to observe anything taking place anywhere the camera is placed. Designed for continuous unattended operation, the all-transistor circuitry of the 501 consumes only 7 watts of power.

SPECIFICATIONS:

- Measures 23/4" x 4" x 7" (excluding lens and connectors).
- Weighs 31/2 lbs.
- Operates on 100-130 volts 50 or 60 cycles, 7 watts.
- Tested at 10° to 125° F.
- Advanced circuitry utilizing 35 semi-conductors most of which are silicon.
- Field affect input circuit for minimum video noise.
- Resolution guaranteed to exceed standards set by 525 line TV receivers.
- RF output 30,000 microvolts adjustable for channels 2 to 6.
- Video output 1.5V p-p composite with standard negative sync (random interlace).
- Viewable pictures obtainable with illumination as low as 1 ft, candle.
- Vidicon controlled light compensation; 150/1.
- Adjustable iris on lens enables use in bright sunlight.
- New long life, sub-miniature vidicon with spectral response similar to Type 7735A.
- Electronically regulated power supply and thermally compensated circuits eliminate change in picture quality when line voltage and temperature fluctuate.
- All parts guaranteed for 1 year (except for open filament on vidicon or breakage).
- Fast, low-cost service always available from our factory in Hoilis, N.Y.

Pre-set adjustable controls include the following: Video gain, video compensation, pedestal level, target voltage, beam voltage, beam alignment, electrical focus, horizontal frequency, horizontal size, vertical linearity, modulation and RF frequency output.

196-23 Jamaica Ave. Dept. S Hollis, N.Y. 11423

mals was seen it's hard to remember them all. John (9U5JH) had along in his car a head light sealed beam light mounted on the end of a short handle with the end of its cord a plug that we plugged into the cigarette lighter on the dasboard of his car. When we saw a pair of eyes in the distance I would snap on the light and zero in on them and keep the light in their eyes until they disappeared into the jungle. Most of them did not try to evade staying in the light. Many many lions, big baboons, antelopes, zebras, rhinos, elephants and best of all quite a few big beautiful leopards setting up on rocks beside the road ready to pounce on anything that happened to pass their way. When we passed them you can bet the windows were rolled up. We did not want a leopard jumping in our car. These rascals usually would just set there watching the car as it passed. A few times we pulled up and stopped parallel to them and I kept the light in their eyes and had a good chance to look them all over. Boy, if we only had a gun along with us, Peggy would have had a few leopards skins towards a leapord skin coat. It would have been so easy to shoot them smack between the eyes and not even leave a bullet hole in their skin. But all we could do was just "look" at them from the safety of our car.

Lions: this was their hunting grounds, they were to be seen at least every half hour. We would see from one to three or four, I mean right beside the road. They were like the leopards-not afraid of anything. The most numerous of all animals was those hyenas. Many other animals were seen. Many of them, not even John knew their name, some looked sort of like our American racoons and opossoms. My flash no pictures was taken I am sorry to say. Even a few very large snakes crawled across the road, probably pythons. This was the real African jungle and I was a little bit on the edge everytime we stopped the car, wondering if it would start again O.K. My only regret was that it was a fast trip without many stops along the way. After the all-night trip from Mwanza and driving all the next morning we arrived at Kitega, Burundi and drove a few miles from town to the home QTH of 9U5IH which was at a missionary settlement on top of one of those hundreds of little hills that you see in Burundi. As a rule the Eruopeans build their homes on top of these hills and the natives build theirs down in the valleys between the hills. The natives lived in typical thatched huts with many many banana trees all around their settlements. I asked John why all the banana trees, thinking they exported bananas, and he said they made banana wine from the fruit. He said this banana wine was very powerful stuff and that great quantities of it was consumed by the natives. We also saw quite a few tea plantations here and there usually on the side of the hills. The temperature was not too bad on top of those little hills. Usually a slow breeze blew during the daytime and at night it was very pleasant, late at night getting a little chilly. John had up a real nice 20-meter quad, maybe it was also 10 and 15 because it was of the center spider construction. His equipment was cleared from the operating table and mine was placed there and tuned up. I was on the air as 9U5JH, the band stayed open until about 3 AM and was open to everybody all at the same time. All my "Gus watchers" were in the pile-up and I had a ball with FB signal reports from everywhere. Nearly everyone saying I was a new country for them, which I doubt since John had always been quite active and many other 9U5's from Burundi had been on for many years. I am a firm believer that, "if you are the rarest thing on the air, you automatically become DX to everyone everywhere, and they will join in the pack just to be working DX. Of course this suited me FB because the bigger the pile the better I like it. A DXpedition wants big business, that's the reason there are DXpeditions you know. John filled up the coffee pot and told me how to heat up the coffee. Milk and sugar was on hand and everytime I got a little sleepy, to the coffee pot I went. John had a nice wife and she was a good cook so there was always plenty of good food there. My stay with John was one of those good ones. The kind you are always looking for when you get away from home. John told me many stories about what has happened there since he had arrived, lots of good ones about lions getting into native huts, gobbling up a few of them, then their lion hunt to get the "man eater". You can be sure these things do happen in deep Africa, they right now have lion trouble in some of the out laying places I am sure. That's it for now fellows, MORE NEXT MONTH.

Waters' Dummy Load and Wattmeter

The new dummy loads from Waters Manufacturing down in Wayland, Massachusetts, nicely fill the amateur need for a dummy load and/or wattmeter that he can depend upon. The two models are basically the same load, but the Model 374 has a built in wattmeter while the Model 384 does not. These loads consists of a structured monolithic 52 ohm non-inductive resistance unit designed to present a constant impedance of 52 ohms over the frequency range from dc to 230 MHz. To provide adequate cooling when large amounts of power are dissipated by the resistor, it is sealed into a steel container filled with oil; a thermostat is also sealed into the container as an indicator of maximum safe operating temperature.

Since the impedance of a load of this type is dictated solely by the physical geometry of the load resistor, once it is sealed into the can, it cannot be adjusted. However, the manufacturer states that the maximum SWR is less than 1.3:1 from dc to 230 MHz,

and tests with a commercial SWR bridge bear this out. The load is somewhat flatter (closer to 52 ohms resistive) on the high frequency bands up to 30 MHz than on the VHF bands, but even at 230 MHz the measured SWR was less than 1.3:1.

The two loads appear to be identical except that the 374 Dummy Load-Wattmeter has a built in rf wattmeter. This wattmeter consists of a semiconductor rectifier and filter network which furnishes a dc voltage to the meter movement from the rf voltage across the load. The dc voltage is connected to the meter through four resistive attenuators to provide full scale readings of 15, 50, 300 and 1500 watts. This instrument is calibrated at the factory with a precision low frequency wattmeter and the guaranteed accuracy from 2 to 30 MHz is \pm 5% of the full scale reading on each range. This means that on the 1500 watt range the reading is \pm 5% of 1500 or \pm 75 watts. The accuracy from 30 MHz to 230

MHz is not stated by the manufacturer because the power readings above 30 MHz will be somewhat higher than predicted. However, the 374 may be used as a relative power indicator up to 450 MHz; above 230 MHz the power input should not exceed 250 watts.

One very nice feature of the wattmeter is that it is possible to run a quick check on the calibration with normal 120 Vac, 60 Hz, line voltage. Immediately after calibration, the technicians down at Waters make a note of the reading obtained on the 50 watt scale when 120 Vac is applied to the input terminals of the model 374 and record it on the rear panel of the instrument. No attempt should be made to correlate actual power levels at 60 Hz with the wattmeter readings. because the circuit is not compensated for this frequency, but it does give the ham out in the field an opportunity to check the cali-

These loads are very useful for loading your transmitter without radiating a signal and for measuring the power output of your transmitter. The Model 384 does not have a built in wattmeter, but it may be used with the Waters 369 Reflectometer to provide accurate, direct measurements of rf power. If your antenna is very closely matched to 52 ohms, your transmitter may be loaded into the dummy load and then switched to the antenna with no changes in final amplifier tuning. If a coaxial switch is used to switch the transmission line from load to antenna, make sure you turn off the transmitter when switching.

The wattmeter is also useful to checking the loss of coaxial transmission lines and

	Are you licensed? yes no
2.	Do you work in electronics? yes no
3.	How long have you been licensed? 0-1 year: 1-5; 5-up
4.	Class license? Nov; Tech; Gen; Cond; Adv; Extra
5.	Do you own an SSB transceiver- yes
6.	About how many hours a week do you devote to amateur radio? Please indicate the approximate percentage of your time you spend on the following:
7.	Bands used: 160M 80M 40M 20M 15M 10M 6M 2M 220MHz 432MHz other
8.	Modes used: SSB
9.	Ham activity: Rag chewing; DX; Traffic; Construction; Contests; other
10.	Do you belong to an amateur radio club- yes no
11.	How much do you expect to spend on amateur radio in the next year?
12.	What major items are you considering purchasing?
13.	You like to build, you say? What construc- tion articles would you particularly like to

A Hint for the TR-4

Occasionally a TR-4 transceiver owner lives near a high power broadcast station that concentrates an antenna pattern in his direction. The result maybe an annoying signal appearing on one of the ham bands.

To eliminate the trouble it must be determined if the interfering signal is the fundamental or a harmonic of the station. Generally this is very easy to do. If the signal comes in loud and clear with no distortion it can possibly be the fundamental. If there is distortion or garble the signal is a harmonic because every time the frequency doubles, the audio signal components double and the station sounds distroted. The frequency of the incoming signal has to be determined so that a trap can be installed in the transceiver.

In my particular case I was troubled by XERB at 1090 kHz coming in on the twenty-meter ham band. It was found that this signal could be almost eliminated by using a series tuned trap across the neutralizing capacitor in the driver grid circuit to trap out the interfering signal.

For this particular station the fundamental was the culprit and a trap was made by from a 37-250 pF trimmer capacitor and 0.1 mH rf choke in series across a 865 pF capacitor (C-43) located in the grid circuit of the driver.

After the trap is installed, listen to the station and tune the trimmer for a minimum signal. If the trimmer closes without tuning through a minimum connect a 100 pF capacitor across the trimmer. The choke in series with the trimmer resonants at 1090 kHz which does the trick. Frequencies not in the broadcast band will take different values which would have to be calculated for the interfering frequency.

Essentially what we have done is to trap out the interfering signal at the grid of the 6EA8 mixer tube. There is no reason why other transceivers using the final amplifier grid coil as the antenna coil coupled to the mixer, and having similar interference problems, could not be fixed by the same method.

Dear Paul:

In your recent editorial you mentioned trying to create more interest in the 2.4 GHz band. You may be interested in the enclosed photographs showing an amateeur tracking experiment organized at Interstate Electronics by Jim Counter (K6AIP). This group successfully locked on and tracked the Surveyor moon probe. The antenna was a surplus 8 foot dish with a home brew feed mounted on a home made tracking mount. The preamp was borrowed from Mel Labs. The receiver is one which the group in the photograph designed and built for NASA. It is called the "General Concept Receiver" and is extremely flexible. It covers 70 MHz to 10 GHz and is triple conversion. Its main application is for reception of narrow band telemetry and doppler from space craft. Tuning is done by a "push button' frequency synthesizer.

The success of the first experiment has resulted in an organized effort to improve the antenna and mount for further amateur tracking experiments.

As you can see the people at Goldstone were quite surprised at the results of this effort.

Sam Kelly W6JTT Garden Grove, California

Kc. or kHz.?

Caen Van Necklaan 227, Rijswijk, Z. H.

Editor, QST:

Unnecessary to say, I'm as full of admiration for your fine paper as everybody else, but just this fact urges me the stronger to protest against one inaccurary. Some time ago you pointed out to all hams that it is much better to speak about frequencies than wavelengths, and the whole world has followed your example. But when speaking about frequencies, we mean the number of cycles per second, in any case the number of cycles in a certain time, and therefore it is wrong to speak about frequency of, for instance, 14,300 kilocycles; one should speak about kilocycles per second, abbreviated kc/s. Nobody would speak about coulombs instead of amperes, but neither should we speak of kilocycles when we mean kilocycles per second.

Now we have a new name for this unit, the Hertz, abbreviated Hz, which was internationally adopted by some congress. As Heinrich Hertz was without doubt an eminent and leading figure in physics, and as it is easier to type and print kHz than kc/s, I think you had better adopt it, too, before you lead all hams in the world astray by the wrong unit, the kilocycle, which you are using to-day.

-W. Keeman, PAOZK.

While agreeing with the author of this letter on the merits of the term "kiloHertz" as a unit of frequency, QST is inclined in this respect to follow the recommendations of the Committee on Standardization of the Institute of Radio Engineers, which is still at work in collaboration with other agencies in the standardization of radio definitions, nomenclature, measuring practice, etc. The current recommendations of that committee gives the meaning "kilocycles per second" to the abbreviation "kc.", exactly as attaches to the abbreviation "kHz." The "kiloHertz" is not yet a recognized unit of frequency either in this country or in the international literature, and for that reason QST does not use it.—Editor.

From QST, page 58, September, 1930.

17TH EDITION of the world-famous RADIO HANDBOOK

- Most comprehensive how-to-build-it source
- Problem-solver for designers & builders

Completely revised and enlarged by William I. Orr, W6SAI. This is the comprehensive communications manual which is the industry standard for electronics engineers, technicans, and advanced radio amateurs. Explains in authoritative detail how to design and build all types of radio communications equipment.

LATEST HOW-TO-BUILD DATA

The new 17th Edition of the RADIO HANDBOOK presents design data on the latest amplifiers, transmitters, receivers, and transceivers. Includes greatly enlarged sections on single-sideband equipment and design, and semiconductors. Gives extended coverage to r-f amplifiers, special vacuum-tube circuits, and computers. All equipment described is of modern design, free of TVI-producing problems.

THOROUGHLY REVISED & UPDATED

Provides a complete understanding of the theory and construction of all modern circuitry, semiconductors, antennas, power supplies; full data on workshop practice, test equipment, radio math and calculations. Includes aspects of the industrial and military electronics fields of special interest to the engineer and advanced amateur. The 17th Edition of the RADIO HANDBOOK provides the broadest coverage in the field—complete information on building and operating a comprehensive variety of highperformance equipment. All data is clearly indexed. 832 pages; $6\frac{1}{2}$ x $9\frac{1}{4}$ "; hardbound. Invaluable for amateurs. electronics engineers. and designers.

What's New for You?

OOP Transistor Notes

\$1FET's I tried the inexpensive Motorola FET's in a number of circuits and found them quite satisfactory. I would use them without hesitation in the second stage and mixer of the 2 meter converter described by K6HMO in the October issue, and would use them for all stages on six or below. They are about a decibel noisier at 220 MHz than the TI plastic-cased units (2N3819), but nevertheless quiter than a 417A at that frequency, which is pretty good for a buck. The numbers are MPF103, MPF104 and MPF105. These are N-channel symmetrical FET's similar to the 2N3819, but with a

220 or 144 MHz preamp using \$1 Motorola MPF105's or \$4 Texas Instruments 2N3819. The \$4 one is about a dB better. Dip the coils to frequency. The input tap is about 50% up, output is 20%. Adjust everything for best NF. W100P got 1.8 dB.

different base. The MPF105 has the highest transconductance and the lowest noise figure. Its best NF is at zero bias, also like the 2N3819. MPF is about a buck; the 3819 is about four. The MPF105 is equal in noise figure to a 6CW4. I got 4.1-db NF at 220 MHz with the best of the Motorola units and 2.5 dB for the best 2N3819.

Fairchild 2N4122: I am really impressed by the Fairchild 2N4122. It isn't more anything than anything, but it is silicon, and it is a good replacement for PADT and such germanium transistors where heat turns out a problem. (Note that silicons may not be very good below zero degrees F, though the germanium transistors get better down as low as you are likely to get.) The 220-MHz NF of 4-5 dB of those I measured beats the Philco T2028 and is about even with the 2N2398 and 2N2494-5, considered very good three years ago. Price under a buck. Also good for audio.

GE16K2: GE's 16K2 is a good NPN silicon, cheap, for local oscillator chains and such. NF is 3.5 to 4.8 dB at 220 MHz for 20 units. It's similar to the Fairchild 2N3563.

TI XM101 vs TI XM10: We've run some interesting comparisons of the TI XM101 (about \$20) and the TI XM10 (about 94c). 220-MHz NF of the 101's was 1.9 dB. One lot of XM10's ran 2.0 to 2.5 dB. The late, lamented, XM05-6's ran about 30% under 2 dB, with 1.5 and 1.75 measured.

150 MHz converter: Last week I made a 150 MHz converter for lab use. With four under \$1 types, 1 had a 3-dB NF. For anything better, another rf amplifier would be needed.

Fairchild 2N4342: I tried out the Fairchild P-channel 2N4342 FET. NF 6 to 7 dB at 220 MHz, which, with a 5 dB second stage, is about even with a short. Don't know if it had any gain or not. I had five, tried only three.

The above notes are all from Hank Cross W100P, who is generally accepted as knowing what he's talking about. The information on prices is approximate and subject to change or error. Get the specifics from your distributor.

Kindly Keyer

Dear Paul.

I have had considerable correspondence considering "The Kindly Keyer" in the July 73". It appears that there were a couple of minor problems in the article as it appeared, which we failed to catch.

First, there are a few discrepancies between the schematic and the p.c. board layout:

Corrections to p.c. layout, page 49

- 1. Q₅ and Q₆ (labels on same) should be interchanged.
- 2. A 33K resistor should be shown between base of Q_5 and emitter of Q_6 .

These are the only real errors which should be straightened out. However, in the case of Q_1 :

- 3. The 100 k could be changed to a 220 k.
- 4. The $.1\mu$ F capacitor could be a .22 F.
- 4. The .1 F capacitor could be a $.22\mu$ F. (These only affect the time constant of the blocking oscillator, and any combination would work, with a different setting of the speed pot.).
- 5. The 82Ω resistor could be attached to +4.5V. (This makes the side tone louder.)

Notice that the order of components in the base of Q_1 is different, but since they are in series, there is no electrical difference. Even a novice should know this, but it seems to bother some!

6. Labels could be affixed to three terminals in Q_1 - Q_2 block as shown.

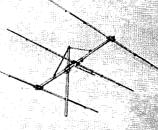

These changes would result in perfect agreement of p.c. board and schematic, but only 1 and 2 seem worthy of mention.

C. LeRoy Kerr, WA6CTK
P.O. Box 444
Montebello. California 98641

stitute had plenty to do on its hands just filling in those areas where the League should have been active, but wasn't. Possibly this was a mistake. I suspect now that many more amateurs might have joined the Institute if it had been formed as a direct opponent of the ARRL, complete with hundreds of appointed officials all over the country to spread the gospel from head-quarters to the grass roots members, hoked-up elections of cardboard directors with no real say or even awareness of the real forces running things, official bulletins, inconsequential "services" and the whole ball of wax.

No, I goofed it. We set up with minimum of overhead, sent inexpensive letters to Congress, and ran the Institute without all the hoopla and big salaries. We also ran it without very many members for I found, to my intense disappointment, that without the Big Show there were very few dollars . . . or members to speak of. I tried telling the straight facts in my editorials, but found myself being called interesting names for trying to ruin the ARRL. Oh, I've centainly been critical of a couple of the top men running the League, no question of it. Few people have noted that none of these gentlemen will face me in public and answer my criticisms. But I've intentionally kept the Institute completely out of any hassel with the League and kept it on its published aim of speaking up for amateur radio in Washington.

All current members will receive a long and detailed account of the history and philosophy of the Institute, as well as a complete and detailed account of the income and expenses. And there'll be none of this vague coverup you find in the ARRL annual report.

How great is the disaster? In August 1966 there were six new members . . . September five . . . etc. There is no question at all that very few amateurs believe that there is any importance in th goals of the Institute. I suspect that the best plan is to not make any further effort to promote membership. I'll do what I can at my own expense to send information about amateur radio to Congress. Barry Goldwater has made some excellent suggestions for getting the most out of the least effort along this line. I'm going to keep pitching . . . sorry I failed to interest very many of you in the idea.

DX Flash

The DXers may be interested to know that as far as WTW credits for countries are concerned that not only do we accept anything as a country that is accepted by any national amateur radio society, but we feel that if a fellow operates from a country then contacts with him should count for that country. We do not feel that we should try to set ourselves up as official arbiters on exactly how legitimate a license is for any

In the U.S. there is little question about licenses. Either you have one or you don't. But once you get off the beaten path it is difficult to set up firm rules. In Nepal there is, the last I heard, one and one only legitimate licensed amateur and that is Father Moran 9N1MM. But other amateurs can and do operate with the knowledge and unofficial consent of the government. This same situation is true in several other countries I have visited . . . and things are even looser elsewhere. It becomes almost capricious to try to set oneself up as the "official" decider as to what is or is not licensed. Hence our decision that if he is there it counts.

WE WANT TO BUY Surplus Aircraft Radio & Test Equipment

We will pay cash or trade you (whatever you need) for the following items:

Test Equipt. Signal Generators.

Measurements Corp. Models 65-8

Boonton Radio Co. Models 232A, 235A.

Hewlett-Packard Co. Models 608D, 612A, 624C.

Military Models. SG-1A, SG-2, SG-13, SG-66A, MD-83A, TS-510A.

Aircraft Navigation & Communication Equipt. ARC-34, ARC-38, ARC-52, ARC-73, ARN-14, ARN-59, ARN-73.

Aircraft Instruments.

ID-249A, ID-250A, ID-251A, ID-351A, ID-387.

We also want late type Aircraft Radio and Radar equipment manufactured by Collins Radio Bendix Radio and Aircraft Radio Corp.

Write, Wire or Phone if you can supply any of these. Ask for Norm Eichner.

Technical Aid Group

The first members of 73's Technical Aid Group are listed below. They are willing to help other hams with their technical problems. If you have a concise question that you think can be answered through the mail, why not write to one of the hams on the list? Please type or write legibly, and include a self-addressed stamped envelope. One question to a letter, please.

If you'd like to join the Technical Aid Group and you feel that you are qualified to help other hams, please write us and we'll furnish complete information. It's obvious that we need many helpers in all parts of the country and in all specialties to do the most good. While 73 will try to help with publicity and in other ways, we want the TAG to be a ham-to-ham group helping anyone who needs help, whether they be 73 readers or not.

Don Nelson WB2EGZ, EE, 9 Greenridge Road, Ashland, N.J. 08034. VHF antennas and converters, semiconductors, selection and application of tubes.

Tom O'Hara W6ORG, 10253 East Nadine, Temple City, Cal. 91780. ATV, VHF converters, semiconductors, general questions.

Stix Borok WB2PFY, high school stu-

dent, 209-25 18 Ave., Baysida, N.Y. 11360. Novice help.

George Daughters WB6AIG, BS and MS, 1613 Notre Dame Drive, Mountain View, Calif. Semiconductors, VHF converters, test equipment, general.

Roger Taylor K9ALD, BSEE 2811 W. William, Champaign, 1ll. 61820. Antennas, semiconductors, general.

Jim Ashe W2DXH, R.D. 1, Freeville, N.Y. Test equipment, general.

J. Bradley K6HPR/4, BSEE, 3011 Fairmont St., Falls Church, Va. 22042. General.

Howard Krawetz WA6WUI, BS, 654 Barnsley Way, Sunnyvale, Cal. 94087. HF antennas, AM, general.

Robert Scott, 3147 E. Road, Grand Jet., Colorado 81501. Basic electronics, measurements.

J. J. Marold WB2TZK, OI Div USS Mansfield DD728, FPO San Francisco, Calif. 96601. General.

Hugh Wells W6WTU, BA, 1411 18th St., Manhattan Beach, Calif. 90266. AM, receivers, mobile, test equipment, surplus, repeaters.

Richard Tashner, WB2TCC, 163-34 21 Road, Whitestone, N. Y. 11357. High school student, general.

Wayne Malone W8JRC/4, BSEE, 3120 Alice St., West Melbourne, Fla. 32901. General.

(Continued from page 4)

to pay for equipment to the movement to form an effective Canadian amateur organization instead of expecting Canadians hams to be a small division of the US ARRL. Incidentally, it sounds like this is an excellent year to visit Canada. From all indications, Expo 67 will be a far more satisfactory world's fair than the one in New York. Maybe we'll see you there.

So there are the special issues of 73 coming up in the next few months. Each issue will also feature the usual selection of what we hope will be interesting, informative and entertaining articles. Be sure to be with us.

Writing for 73

So many people have sent for copies of our booklet, "Writing for 73," that we've had to reprint it. If you've thought at all about writing for publication, why not send us a self-addressed business envelope and we'll mail one out immediately. I have also compiled a list of articles I'd like to have for 73. Please mention if you'd like the list.

TAG

The Technical Aid Group (TAG) is starting to help hams with their technical problems. However, we need many mere helpers to be able to work effectively. If you feel that you're competent to help, and have a few extra hours to devote to helping other hams, we'd like to hear from you. Your main reward from this work will be a sense of satisfaction and a little publicity, though there are a few other benefits. Please write for details.

. . . Paul

New Products and Books

Eico 711

E.co's newest communications product is their 711 Space Ranger Short Wave Communications Receiver. It covers .55 to 30 MHz with a BFO, bandspread, S-meter. Its cabinet is attractive enough for the living room. In kit form, the 711 is \$49.95; wired, it's \$69.95. You can get more information from Eico, 131-01 39th Ave., Flushing, N. Y.

Denson Catalog

A surplus catalog to really make you drool is the new, 160-page catalog from Denson Electronics Corporation. Al Denson, W1BYX has spent a tremendous amount of time photographing, listing and organizing his stock and the results are very impressive. Al specializes in television equipment, but the catalog contains surplus and used equipment of every description. Of special interest to the TV ham is a complete bibliography of articles on ham TV and many reprints of articles on TV in the catalog. The catalog costs 50c; it's worth far more than that for the reference data alone. Denson Electronics, P. O. Box 85, Rockville.

Oscilloscope Measuring Techniques

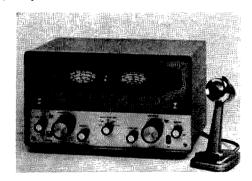

The serious electronics experimenter knows that an oscilloscope is the most valuable piece of equipment available for testing. However, few hams take full advantage of their scopes. An excellent book about scopes and their uses is Oscilloscope Measuring Technicques by J. Czech. The book is the English edition of a book published in German by Philips, and it is very complete. The first 250 pages of the book are devoted to scope circuits and construction, the next 120 pages to general measuring techniques, the next 170 to specific techniques and the last 50 pages to scope photography and projection. The book costs \$15.80 and is available from Springer-Verlag, 175 Fifth Ave., New York, N.Y. 10010.

Low Cost VHF Antennas

A new line of low cost VHF "Space-Saver" antennas for 120-480 is being manufactured by International Crystal Mfg. Co. The antennas feature full performance, solid molded bases, ease of installation. Mobile and fixed base units include a vertical mobile for \$5.25, vertical ground plane with universal mount \$8.50 or with pipe mount \$10.95, dipole with pipe mount \$11.95, and the attic or base antenna with universal mount for \$6.95. Special coax cable kits for use with antennas are priced at \$3.95 and \$4.95. For complete information write International Crystal Mfg. Co., Inc., 18 North Lee, Oklahoma City, Oklahoma 73102.

RCA Receiving Tube Manual

The new edition of the RCA Receiving Tube Manual (RC-25) contains over 600 pages of information on electron tubes and their uses. The first 100 pages contains a wealth of data on general characteristics of tubes and how they should be used. The next 400 pages lists all receiving tubes made by RCA—virtually all receiving tubes—with all of their characteristics. The last section of the book contains many applications of tubes, with specific circuits and description of how they work. The book is a tremendous buy at \$1.25. Buy at your dealer, or order from RCA Commercial Engineering, Harrison, N. J. 07029.

Hammarlund HQ-205

The new Hammarlund HQ-205 is a general coverage receiver with a built-in 5 watt 10 meter or CB transmitter. Electrical bandspread is on 80-10 meters as well as CB. The receiver tunes .540-30 MHz. It includes a variable BFO, Q multiplier, NL and S meter. Price is \$259.00. You can get more information from Hammarlund Amateur Products, 73-88 Hammarlund Drive, Mars Hill, N. C. 28754.

COMPRESSION AMPLIFIER \$29.95

These government surplus limiting amplifiers offered at a fraction of their cost and they are brand new unused. Input & output impedance of 600 ohms. self contained 115 volt 60 cycle power supply. Gain 36 db plus or minus 1 db. Upgrade your shack for professional performance with this beautiful rack panel commercial grade equipment. DB out meter on front panel.

3314 Diamond Drive El Paso, Texas

Designs & Construction of **Electronic Equipment**

In this new book by George Shiers, the author acquaints beginners with the processes and problems of designing and building electronic equipment while at the same time providing experienced technicians and designers with much practical assistance. This text covers chassis design and layout, panel layout, component boards, wires and cables, connection methods, printed circuits, fasteners and finishes. It also provides a great deal of practical information on circuit protection, interference, shielding and grounding and environmental probsuch as heating, cooling techniques and corrosion. This book is filled with excellent illustrations and drawings; a number of useful tables are also included for the prospective electronic designer. For the amateur who builds his own equipment, this book provides a wealth of very useful and practical information. \$14.00 from your local bookstore or write to Prentice-Hall, Inc., Englewood Cliffs, New Jersey 07632.

G and G Catalog

A new 24-page Catalog of Communications Electronic Equipment has been published by G & G Radio Supply Company, 75-77 Leonard St., New York, N. Y. 10013. The catalog, which is fully isllustrated and contains complete technical information, covers military surplus receivers, transmitters, power supplies, test sets and associated equipment, including dynamotors, tranmitting crystals, special purpose tubes and headsets. Copies are available from G & G Radio Supply Company for 25c refundable with first order.

Amperex Components Catalog

Amperex makes some very nice electronics components that aren't well known to most readers of 73 because they aren't handled by any of the distributors we usually buy from. However, they've put out a catalog that should be of interest to all designers and buyers for manufacturing companies. The catalog contains condensed listings of electrolytic, foil, ceramic and variable capacitors, linear and non-linear resistors, speakers and knobs. Copies may be obtained by writing on company letterhead to Amperex Component Division, Hicksville, N. Y. 11802,

Directory of Electronic Circuits

In his new book Matthew Mandl presents a unique and valuable took for amateurs, technicians and engineers; a very comprehensive directory of more than 150 circuits used in all fields of electronics. Each of these circuits is completely analyzed in a very readable manner, and typical circuit values are provided along with the equations and formulas that describe their operation. To provide a more useful tool, the author has grouped the circuits into general categories and provided a detailed cross-reference system throughout the book. While the emphasis has been placed on transistorized circuits, vacuum tube circuits are detailed for comparison purposes or where they find a special application. Some of the categories of circuits are amplifiers, modulation and demodulation circuitry, filters, attenuators and pads, oscillators, power control and supplies and pulse circuits. In addition, a handy glossary of the most frequently encountered technical words is provided along with an appendix containing unit values, conversion factors, color codes and other useful electronic information. In all, this book is a very useful text that should be of interest to old timer and novice alike. \$10.00 from your bookstore or write to Prentice-Hall, Inc., Englewood Cliffs, New Jersey 07632.

FET Projects

The latest book in Motorola's line of HEP publications in Field Effect Transistor Projects. It is a step-by-step instruction manual on projects that can be made with Motorola HEP FET's and other components. The projects are a vibrato for electronic musical instruments, an audio mixer, a timer, a crystal oscillator (such as a 100 kHz calibrator), and hi-fi preamplifier, and a dc voltmeter. The book also includes a short section on FET theory and construction practices. Complete building instructions are given for each project, including layouts.

Quaker Electronics Tech Manuals

Quaker Electronics has published a catalog of technical manuals they have for sale. The catalog also lists a number of very common pieces of surplus for which they have schematics. You can get the catalog for 25c from Quaker Electronics, P. O. Box 215, Hunlock Creek, Pennsylvania.

27 37 47 57 67 FORGET 'EM ALL!

The woods are full of competitors who try to tell you how many millions they have, how big-hearted they are, how much they'll pay you for your equipment—and blah, blah, blah, FORGET IT! FORGET it. FORGET it. FORGET when you do business with Number Onel What others promise—COLUMBIA delivers! We want to buy electronics and test equipment—both military and commercial. If you have a single piece or a trainload—we'll pay you the top dollar for that equipment—bar none! We airmail your check the same day your goods arrive. On top of that—we pay the freight! Save time, money, headaches and aggravation! Tell us what you have—what you want! And P.S.: Do it today!

de W2NSD|1

never say die

CB

The CB licenses are now down to about 800,000 and the FCC reports that renewals are running about 12%. It would appear that the tide has turned and that the CB channels are changing from hobby use to business, as was originally intended by the FCC.

DXing

In answering the OSL's to my operations at FO8AS, VR2FD, FK8BG, 5W1AZ, 9N1MM and other exotica I have been surprised, to be polite about it, by the number of cards coming in with time and date in local terms instead of GMT. I'll be blunt: this is STUPID. I work four or five stations a minute and when I get a card in Mountain Standard Time I have to either make the conversion to GMT or else start looking through the logs until I find the contact. Perhaps one third of the cards have the time and date exactly right . . . and one third have the right date and the time within fifteen minutes (about 100 or so contacts to look through in the log). One third are way off with the date wrong and time either very wrong or else in local time. About 5% I just couldn't locate in the logs at all. Come on fellows, use correct GMT time and date.

ARRL

Perhaps my approach to the League has been a bit critical, but implicit in this was a constructive intent. I do believe that we should have an organization to represent the amateurs. Many amateurs firmly believe that this is the present function of the League. Unfortunately this is a delusion. The League certainly could assume this function and I think that it would be very advantageous to amateur radio if the mem-

bers of the ARRL made every effort to achieve this end.

You see, right now amateur radio has absolutely no representative organization. We stand just about alone as a major user of the radio spectrum without any such official representation. The other vested interests see to it that they have a good loud voice in Washington and they are right in there putting on the pressure whenever anything comes up that could help or hurt their groups. They work with the government agencies, with the administration, and with Congress to make sure that everyone knows their side of things and that they get the best shake.

A few ARRL directors have for years been trying in every way they could to get the League to open a small office in Washington and set up a lobby for amateur radio. No adequate reason has ever been given for killing off these attempts. The directors I have talked with about it felt that the main reason was that the HQ top brass didn't want to take any chances on the seat of power leaving them . . . and they didn't want to leave the nice green fields of Connecticut for the concrete of Washington.

They are probably right. Once something is started in Washington it is bound to take over for that is where the action is . . . that is where things happen. I suspect that if our ARRL were centered in Washington and had the ear of the FCC, the administration, and Congress that ham radio would not be in the terrible fix it is today. One of our country's most valuable resources is amateur radio and our government and Congress should be constantly made aware of this.

Loyal ARRL members would do well to ask their directors to press for representa-

(Continued on page 110)

ROHN.

Big name in towers

ROHN TOWERS have become the accepted standard of excellence throughout the world — meeting the needs of the communication, broadcasting, transportation, oil, utilities, manufacturing and other industries, including home TV and amateur needs.

Computer engineered and designed ROHN TOWERS are produced in ROHN'S vast manufacturing complex utilizing the latest equipment and methods. Convenient warehousing facilities at strategic locations plus world-wide representatives and complete turnkey tower erection service . . along with a complete line of tower accessories, light ing systems and microwave reflectors make ROHN the complete tower line throughout the world.

Representation and Distribution Worldwide For further information contact

Editors

Ramblings

Editing a magazine is a peculiar occupation at best, and editing this magazine is probably even more peculiar than most. It often seems like a big, unreal game. However, even though the game is a hectic and nervewracking one at times, I must admit that I've enjoyed most of the last three years while I've been at 73, and particularly the last year or so while I've been editor. I've enjoyed meeting many interesting peopleauthors, readers and advertisers-and have learned much about electronics, publishing and ham radio. So it's with mixed feelings that I announce that this is the last issue of 73 that I will edit. I've tried to improve 73, but know there's far more that can be done. That's why I'm happy that the new editor will be Jim Fisk W1DTY, ex-WA6BSO. KR6JF, K4RPW, K3CPJ, and KA9MF. Jim is well known to all 73 readers for his many articles and books. He is a DX'er (SSB and CW) as well as an avid experimenter, home-constructor and UHF-VHF fan. Jim is highly competent and I know that 73 will improve steadily with him in charge.

As for me, I'm joining General Radio Company in Concord, Massachusetts, but hope to keep my hand in ham radio publishing by editing the new 73 column. "What's New for You?" and by writing. Until then.

Al Freddy Newham WNIECCH Flagrant, New Hampshire

The Super Duper Super

When my ticket arrived from the FCC, I was really up against it—I had to have a good receiver. I was all set in the transmitter department; one of my good buddies from across town donated a slick crystal controlled job with a pair of 199's in the final. I couldn't come up with any homebrew receivers that matched the goodies I had in the junk box after searching through the current ham magazines, so I decided to use a little ingenuity and the parts that I had on hand.

I'll have to admit that this design is not completely my own; it evolved from several

of the articles that I read before starting this project. Here again my good buddy was a big help—he gave me a whole carload of ham literature. After drooling over the Marconi loose couplers, Grebe receivers and REL transmitter kits in the ads, I did a lot of reading about receivers. With the helpful hints of these articles under my belt, and a lot of sweat over the kitchen table, I came up with the two tube super duper super shown here. It may not be quite up to par with the Colland's Super Century or the Crutchcrafter's SD-150, but it runs a very close second. And besides, it didn't cost

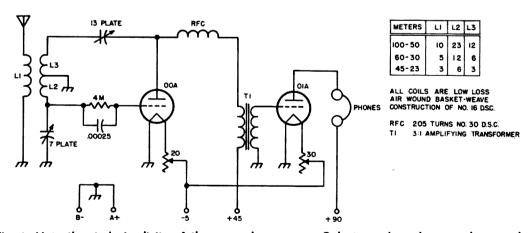

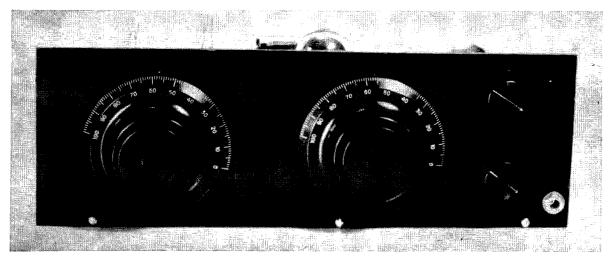

Fig. 1. Note the stark simplicity of the super duper super. Only two tubes, three condensers, three resistors, an amplifying transformer and some wire are required. For details on how to wind the coils and the rf choke, consult the text.

6 73 MAGAZINE

The super duper super. The large dial to the left is the rf tuning control; the large dial to the right controls regeneration. For best results these two knobs must be worked together. The two knobs on the far right control the amplification of the detector and audio stages.

1/10 as much.

The basic plan I had in mind was to come up with a receiver that was simple to build and use and that could be duplicated by other hams with a junk box like mine. I opined that there must be a lot of fellows in the same boat as me—lots of parts but no circuit that they'll fit. And then too, I didn't have a whole lot of goodies; in fact, at times I wondered if I would be able to come up with a workable receiver with the things that I had. As you can see from the schematic, this little job only uses two tubes, three condensers, three resistors, one transformer and some wire; you can't get much simpler than that!

Basically the super duper super consists of a regenerative detector and an audio amplifier. I experimented with various methods of controlling the regeneration in the detector, but finally decided that the Weagent capacitive regeneration control gave the best results. The circuit seemed to be the easiest to tune and didn't move too far off frequency when I pulled my hand away from the dial.

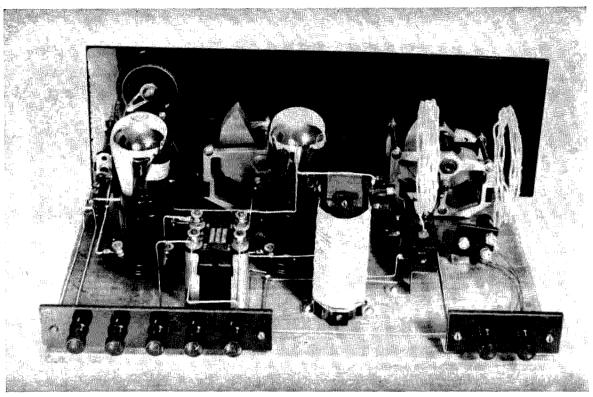

I heard someone say once that much of a receving set's performance depends upon the correct choice of the grid leak and my experimenting bears this out. It must be quiet and must have a resistance of four or five megs for CW work. For phone work (after I get my general ticket), values as low as 1.5 megs seem to work quite well. The grid condenser was also determined by cut and try. I found that a grid condenser

capacity of a micromicrofarad per meter is not too far wrong for the 00A detector. I didn't use this value however because all I had in the junk box was a 0.00025 unit.

The tuning condensers are just as they came out of the junk box. There are no markings on them so I don't know what their capacity is, but the rf condenser has 7 plates and the regeneration control has 13. Actually, almost anything will work here; all you'll have to do is change the number of turns in the coils.

And the coils-they are the most unique part of this whole design. After scanning the ads and the ill gotten gains of my broken piggy bank, I decided that I'd have to use air wound coils and forego the nicety of coil forms. From what I have heard since, this was probably a good decision; most of the bakelite and hard rubber forms are pretty lossy on the short waves. I managed to glom on to a couple of rolls of D.S.C. (double silk covered to the uninitiated) annunciator wire and decided to use that for the coils. By evenly spacing 13 large finishing nails around the perimeter of a 3 inch circle, I formed a jig for winding my basketweave coils. By weaving the wire around the circle of nails, I ended up with a strong coil that was easy to handle. A raid on mother's sewing basket provided some heavy cotton thread to tie the turns together.

To cover the various wavelengths that I am interested in I had to have some method of plugging in different coils. A home made plug in coil arrangement was made by mounting banana plugs and jacks on a

The working parts of the super duper super. The antenna coil is on the far right with the rf and tickler coil to the left. The large upright object in the foreground is the Newham special rf choke. The two terminal strips on the back edge of the apple crate provide connections to the batteries and antenna. Note the geometric layout of the wiring which contributes so much to the set's performance.

couple of bakelite strips. At first I laid out the strips nice and even with the center tap right in the center of the jack bar, but this led to some quick shuffling when changing coils—you couldn't tell when the tickler was plugged into the right two holes. A modification moved the center tap a little off center so I didn't have to count turns every time I changed wavelengths.

The antenna coil was mounted on another chunk of bakelite which pivots on a brass angle support. With this arrangement I can vary the coupling between the antenna and rf coil for best results. This is a little ticklish until you get used to it because when you put your hand over the panel to move the antenna coil, everything changes frequency. However, with a little practice you can almost tell ahead of time which way the tuning is going to go.

The rf choke was a pure stroke of genius if I do say so myself. The first efforts resulted in a whole bunch of dead spots in the tuning range. That is, spots where the detector refuses to give out with nary a whistle. I don't quite understand all the

ramifications of these dead spots, but I'm working on it. Anyway, the most suitable rf choke I found consisted of 205 turns of number 30 S.S.C. (single silk covered) lump wound on a home made form. Losses are apparently not too important in an rf choke so I made a form by screwing four four inch strips of bakelite to one inch squares of orange crate wood.

After building the complete receiver on the kitchen table, I had to come up with some more portable way of building the finished product. Mother didn't take too lightly to the screw holes and soldering iron burns in the table top, and besides, how was I going to get the table into my shack? The family had to have someplace to eat. Except for a little spilled soup in one of the condensers, the super duper super made it through this crucial period with flying colors. I can't say the same for its originator—for a while I thought ham radio would be banned forever from the Newham house-hold.

A couple of raids on the city dump yielded the rest of the material I needed to build

the super duper super into one compact table top package. The side of an old apple crate served as the bottom and a piece of bakelite from an old Army surplus aeroplane spark transmitter (Mark II) was used for the front panel. All the parts were carefully laid out on the apple crate and then wired together with solid number 16 bus wire. I took great care to make sure that all the wires were parallel to the sides of the apple crate and to make sharp 90 degree bends when turns were necessary. This layout works pretty well down to wave-lengths of 23 meters, but below that performance is not so hot. My good buddy said something about lead length? I don't understand this at all because everyone knows that the shortest distance between two points is a straight line, and all my wires are perfectly straight. I am usually a pretty modest fellow, but the wiring job is magnificant in its geometric beauty, even if it doesn't work on the ultra highs below 20 meters.

The super duper super is a real dream to use. It only has four controls and only two of these have to be tuned at any one time. It only takes about eleventeen hours to get the proper technique down pat. Almost

everyone who has had a chance to use the super duper super has been surprised at its performance. It doesn't surprise me at all, I knew it would work all along. After all, it is based on many proven designs. It has surprised some hams so much that they went away mumbling to themselves. Naturally all this pleases me very much because this was my very first ham project.

Now that I have been on the air several months with my twin 199's and super duper super, the junk box is starting to fill up again. I now have lots of tubes, amplifying transformers, condensers and even a couple of little doodads marked 2N384. My good buddy claims that these miniscule little gadgets will replace the tubes in the super duper super, but I don't hardly see how-they only have three connections. Anyway, I'm working on it and I'll have a full report for all you readers in a subsequent article. ... WN1ECCH

A Toroidal VFO

Gene has made an excellent VFO using a toroidal inductor. This VFO has many interesting construction ideas.

Many advantages can be gained by using toroids in amateur radio equipment. Their small size and high-Q head the list of reasons why they are seeing more and more applications today.

No longer is it necessary to use a four or six inch square box to house the big ceramic coil in the home-made VFO. No longer does the circuit stop oscillating when we attempt to reduce the box size, now that we have toroids. One of these %-inch-diameter gems can be mounted right on a printed circuit board along with the transistors and capacitors which make up a VFO circuit.

A transistorized VFO employing a toroid coil was described by Jo Emmet Jennings W6EI in 1963. Del Crowell, K6RIL sparked current enthusiasm with this recent excellent article from which our circuit (and several cores) were borrowed. In this

Circuit

A conventional Clapp oscillator is used, feeding an emitter-follower buffer stage (Fig. 1.) High frequency NPN transistors such as the 2N697 are used for the oscillator and buffer stages. Temperature compensation is provided by the 75 pF NPO type ceramic capacitor. The relative values of this capacitor and the 100 pF silver mica capacitor may be varied experimentally to provide flexibility in achieving optimum compensation.

An rf probe and vacuum tube voltmeter are indispensable when substituting transistors and making circuit adjustments for optimum output. Approximately 0.3 to 0.5 volts rf should be measured at the emitter of

²A Stable VFO or VHF or HF-73 Magazine, November, 1966.

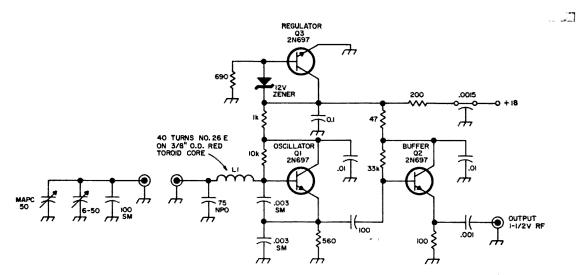

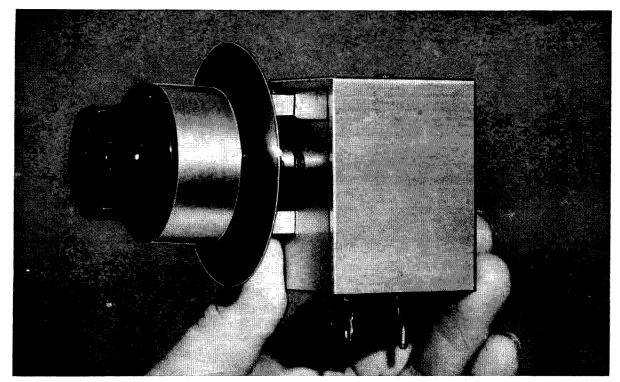

Fig. 1. Schematic of the VFO and power supply. Regulation is provided for both the oscillator and buffer. If more rf output is required, a tuned circuit (toroid, of course) can be installed in the emitter of Q2 in lieu of the 100 ohm resistor.

article is described a practical approach to the construction of a very compact and dependable VFO. The mechanical work required to fabricate the aluminum housing can be done with the simplest hand tools available in most ham workshops.

¹The Transistor Radio Handbook—Editors & Engineers Ltd.

The completed VFO with dial ready for calibration. One screw holds the cover in place. Trimmer capacitor and feed-throughs are used to secure the VFO to a chassis.

Q1. Decreasing the 560 ohm emitter resistor will increase the output up to 1½ to 2 volts whereupon oscillation will stop. The oscillator Q1 should be operated at the lowest emitter current consistent with obtaining approximately 1½ volts output at the emitter for Q2.

The regulator transistor, Q3 is an audio type NPN in a shunt regulator configuration. In the author's circuit, a 2N697 rf transistor was used because it was available. The zener diode clamps the base-to-collector voltage of Q3 to the value selected for VFO operation; in this case 12 volts. This diode may be of the inexpensive ¼ to 1 watt variety. Power for the VFO was obtained from a 6.3 volt transformer and a conventional voltage doubler circuit which provides a peak voltage of about 18 volts.

This VFO configuration may be used at any frequency from 1 to 10 MHz by selecting proper values for LI and its associated frequency determining capacitors. However, in the author's application, the frequency range of 3.5 to 3.65 MHz was required for doubling to the 40 and 20 meter bands.

Assembly

The various parts of the VFO are shown

in the photos. Four #4-40 screws hold the component board in place. The piston-type trimmer capacitor to the right is a Cambridge Thermionic Corp. CS6-50. It is externally adjustable and is used for band setting as well as for securing the VFO housing to a chassis. Positive 18 volts enters via the feed-through capacitor. Centralab Type FT-1500, which aids in mounting the VFO, as does the rf bushing, USECO #1433, to the left in the photograph.

A frequency spread of 150 kHz is achieved with a Hammerlund Type MAPC-50 tuning capacitor. The type capacitor having a ¼ inch shaft extension should be used.

Component Board

A phenolic or glass-epoxy board, 1/16 inch thick is used to mount the components. Fig. 3 shows the position and identification of the parts. In the VFO illustrated, a prepunched phenolic board was employed. Transistor sockets are used to provide greater flexibility in experimenting with different transistors. No deterioration in frequency stability was experienced when using sockets for the oscillator stage due to the "swamping effect" of the large 3000 pF silver mica voltage dividing capacitors.

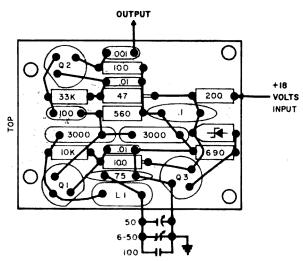

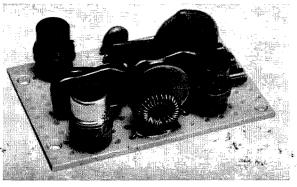

Fig. 2. Component identification is shown here. Because of the small size of the assembly, component leads may be simply bent over and used as indicated, instead of a printed circuit.

Housing

The objective of our VFO design was small size and simple mounting. For these reasons, a special housing had to be built because no commercial box or chassis was found suitable. The scrap pile of a local window glass shop provided rectangular aluminum tubing measuring 1-¾ inches by 4 inches outside. Two "U" shaped pieces were cut from the rectangular tubing so that they precisely "nest" together. One #4-40 machine screw holds the cover in place.

Brackets for mounting the component

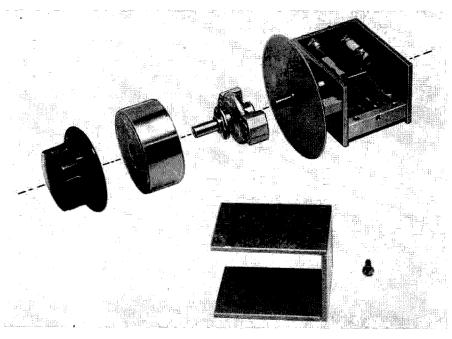

The VFO component board. Pre-punched phenolic material is convenient for the amateur constructor, however, a printed circuit board would improve appearances and provide a little more freedom in making the most desirable component spacing.

board were cut from aluminum scraps and glued in place using epoxy cement. While epoxy provides a valuable fabrication technique, one should not depend on cemented joints for electrical connections. The ground lead from the component board should be brought out and soldered directly to the tuning capacitor terminal as well as to a lug under the piston-type trimmer.

Tune Up

When using a toroid coil core it is impossible to use a grid dip meter in the conventional manner for verifying the frequency of a tuned circuit. This is because the flux of the coil is almost entirely contained within the closed core. Therefore, prior to ce-

Exploded view of the VFO and dial drive mechanism. Two Jackson Bros. planetary-vernier drives provide a 36:1 ratio. Leads to the tuning capacitor and feed-throughs are soldered after installing the component board.

menting the coil in place on the component board, it should be suspended by its leads which are left about 1½ inches long. These leads and the coil form a loop to which the grid-dipper may then be coupled.

After verifying the proper frequency of the tuned circuit, power should be applied with the regulator transistor Q3 only in place. Positive 12 volts dc will be measured at the collector of Q3. A check of the regulator under load can then be made by temporarily placing a 150 ohm resistor between the emitter and collector terminals of the buffer socket. This resistor, together with the 47 and 100 ohm resistors in the circuit, will present a total load of 300 ohms which will draw 40 milliamperes from the regulator, simulating about 100% overload conditions. The regulated 12 volts should show no discernable change under these conditions.

On the Air Tests

Excellent signal tone and stability are obtained from this VFO. The construction techniques used provide maximum immunity from mechanical shock and electrical transients. Long term stability is also achieved by negligible component heating and superior dissipation afforded by the sturdy housing.

A new era of VFO refinement is made possible by the toroid coil. The amateur constructor is well advised to include toroids in his present day projects.

. . . W4BRS

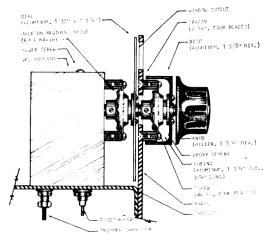

Fig. 3. Cross-section of dial drive mechanism. This arrangement is used in several commercial SSB transceivers. Spacers 7/16 inch long and taped for #4-40 screws hold the drives in place. The aluminum knob nearest the panel provides fast rotation (6:1 ratio) while the conventional knob provides slow speed (36:1 ratio).

Transceiver CW Filter and Monitor

An inexpensive and simple transistorized accessory unit for improving the CW performance of any transceiver.

Just about every transceiver on the market still lacks adequate built-in provisions for CW work—that is, a CW keying monitor and sharper IF or audio selectivity for CW. The author previously built a tube-type accessory unit that could be used with almost any transceiver to provide these functions. However, being an "outboard" unit it was not suited for use in mobile or portable applications. What was needed was a minaturized version which could be tucked away inside a transceiver case.

Circuit

After some experimentation, the author came up with the circuit shown in Fig. 1. Transistors Q1, Q2 and Q3 comprise a so-called "active" audio filter which allows a good deal of selectivity to be obtained by

only RC circuitry. Essentially Q1, and the network in its base circuit make up a low-pass audio filter while Q3 with its network comprise a high-pass filter. The combination of the two circuits produces the selectivity characteristics shown in Fig. 2. The filter can be used between any two low-level, moderate to high impedance points in a receiver audio circuit.

The dashed line in Fig. 2 indicates the ideal if selectivity which a 2 kHz mechanical filter might provide. As can be seen the audio selectivity provided by the three stage "active" filter is a considerable improvement, at moderate attenuation levels, for CW work. If the graph were expanded to cover higher attenuations than 25 dB, it would be seen that the skirts of the active filter flare out beyond those of the mechanical filter. So, while the active filter will by no means pro-

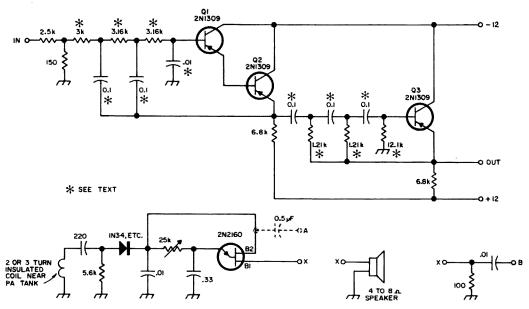

Fig. 1. Filter and monitor circuit which may be used with an SSB transceiver for excellent CW hamming. The -12 and +12 voltages may be obtained from any well-filtered point in the transceiver.

73 MAGAZINE

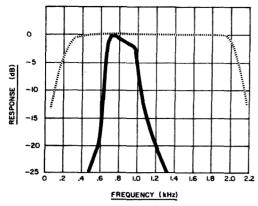

Fig. 2. Approximate frequency response of the filter shown in Fig. 1.

vide the same steep skirted selectivity of a narrow crystal lattice or mechanical filter, it does provide enough selectivity, in a very simple form, for effective CW work.

The CW monitor is rf actuated and uses a unijunction transistor in a relaxation type oscillator circuit. The 25 k potentiometer is used as a tone control. A 10 k fixed resistor could be substituted for further simplicity. Output for headphones can be taken from either points A or B. If the outputs from the filter and monitor are parallel to be used with a pair of headphones, some experimentation will be necessary with the coupling condensers at points A or B to find a value which gives sufficient output level without loading the filter unduly (depending on headphone impedance).

The tone from the monitor, like any relaxation oscillator, is hardly very easy on the ears but satisfactory for the occasional CW user. The CW monitor shown in Fig. 3 is suggested if a smoother note is desired. The 12 volts necessary to power the circuit could be obtained from a RF pickup coil and rectifier, as with the unijunction type monitor, or from some point in the transmitter which provides 9 to 12 volts under key-down condition (across the cathode resistor of a rf stage in a grid-block keyed transmitter, for instance.)

Construction

Construction is simple and inexpensive. No adjustments, other than the tone control, are necessary.

How compactly the unit can be constructed depends solely upon the builder's ability to compact components on a perforated circuit board. Except, of course, for the rf pickup

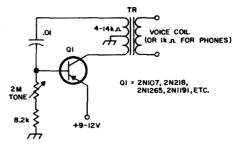

Fig. 3. Another tone oscillator which may be substituted for the one shown in Fig. 1.

coil which must be placed by the PA tank coil, the unit will fit on a 2" x 2" perforated board.

All the transistors used are of the \$1 variety. The only components that are critical are the resistors and condensers starred in Fig. 1. If the selectivity characteristics of the filter are to be attained, the resistors must be of the 1% tolerance variety. The condensers must also be matched as closely as possible using, for example, a capacitance bridge or meter. If "off-the-shelf" 10% tolerance resistors and capacitors are used, performance will likely prove disappointing.

A great many, if not almost all, of the components necessary can be obtained by buying several of the computer boards available at three or four per dollar from various supply houses.

Usage

The unit can be wired into a transceiver so that it can be switched in and out of audio chain in the receiver. A still simpler, "no-holes" approach for those who only use headphones on CW and who have a medium or high impedance headphone jack on their transceiver is to replace the headphones jack with a multiple circuit unit, such as shown in Fig. 4. Plugging the headphones in the jack disables the loudspeaker and the filter and monitor are in the circuit ready for CW operation.

WIOOP's Converter Converter and modified BC command set.

The Converter Converter

Here's an intermediate converter for use between a UHF converter and a receiver tuning the broadcast band. It uses an inexpensive field effect transistor as a mixer for simplicity and excellent resistance to overloading.

A few weeks back I picked up the BC-band version of a command set at one of the local auctions. Now this is one of the nicer (and rarer) of the ARC-5 or 274-N series. It tunes 0.52 to 1.52 something or others (as this is about 23 years old, I guess they are

Fig. 1. Simple version of the Converter Converter by WIOOP. This is designed for covering 14.0-14.4 MHz, with 1.0-1.4 MHz output.

megacycles) with divisions every ten kHz and about thirty turns of the knob to go the range. The intermediate frequency is 239 kHz and it has the same sort of variable-coupling cans that are used in the BC453, so sharpness is easily obtained.

With such admirable selectivity and bandspread, it seemed a shame that it couldn't be used to run one or more of my UHF converters into, so as to have a permanent setup for scanning 431.95 to 432.4, for instance, while working or trying to work another band. While it is hard to get any image rejection with a second if of two or three hundred kilohertz, there should be no trouble in doing it with the receiver tuning 1 to 1.5 MHz. This converter was made for that purpose. My six, two and 432 converters have a nominal intermediate frequency of 14 MHz, while that for 220 tunes 16 MHz down for 220 up. By using crystals providing beating frequencies of 13 and 17 MHz the ARC-5 tunes forward on all bands, which simplifies the mental arithmetic a slew. (A slew is an archaic unit between three and ten dB.)

The oscillator uses surplus crystals at half frequency because I and Meshna had them. The mixer has an FET, since it made the whole business simpler. The 2N3819 (roughly the same as the TI-S34) can be thought of as a super-6CW4, or maybe a super-6CB6 with poor screening. It is quiet, it oscillates nicely at three hundred megohertz with only the leads to a twenty meter tank

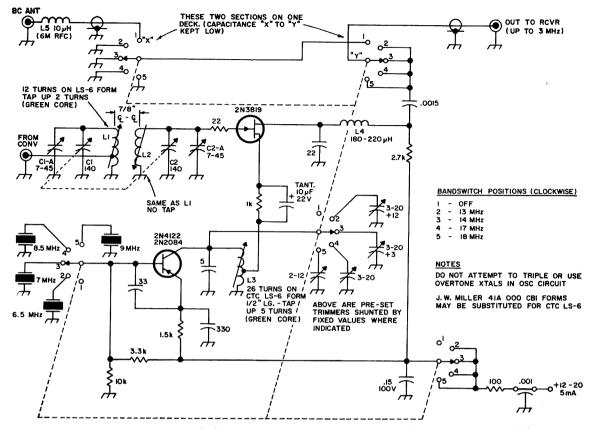

Fig. 2. More complete version of the Converter Converter, with band switching. Shield the quartz crystals if you live within 10 miles of a TV station.

circuit, and the gain, while less than overwhelming, is adequate. According to the manufacturers specifications, the currents and voltages could be almost anything, but that is no problem for the man who is making only one gadget, because the values can be tailored to the particular FET. Suppose we set up with a six to twelve volt battery on the drain (plate) and gate and source grounded to the negative terminal. We measure a current in the drain lead-it might be anything from 2 to 20 mA. For mixer operation, the FET should be turned all the way on only a bit of the time, and if we are trying to operate as a squarelaw mixer the gate voltage should swing from cutoff up to zero bias with oscillator drive, giving an average current about 40 percent of the zero-bias value, with drive, and a quiescent current 25 percent of the zero bias value. We can find the proper operating point by measuring the bias voltage required for one fourth the zero bias current, (no signal) and then setting things up so the source (cathode) resistor has that

*Measure through a good rf choke to avoid changing the amount of injection.

much voltage across it when the oscillator is driving the mixer. My 2N3819 had 4.5 mA at zero bias. It also had UHF oscillations in the circuit, so I put that 22-ohm resistor in the gate lead . . . anything ten to fifty ohms would probably do.

With the second preselector tank shorted (I jammed a solder lug into C2) the current with oscillator going was 1.6 mA, but with

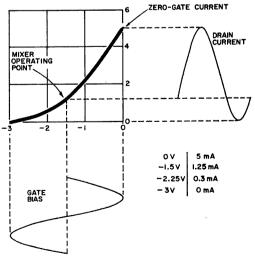

Fig. 3. Operation of the FET mixer.

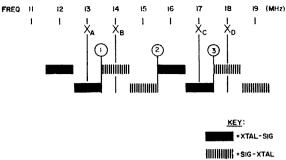

Fig. 4. Coverage of the Converter Converter. If the receiver tunes 0.50-1.50 MHz, there is no gap in coverage. If the receiver tunes 0.52-1.52 MHz, there is a 40 kHz gap at (1) and (3) and overlap at (2). Of course, if $X_{\rm B}$ and $X_{\rm D}$ are 40 kHz low, there is no gap. Coverage is 11.5-19.5 MHz. The coverage W100P wanted was 12-12.4, 14-14.4 and 16-15.5 MHz (the last backwards, for a 220 MHz converter with 236 MHz local oscillator.)

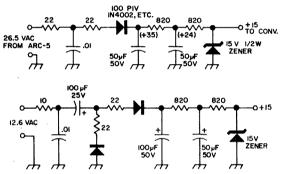

Fig. 5. Two suggested power supplies. The top one operates from 26.5 V ac from the command set and is the one WIOOP uses. The bottom one operates from 12.6 V ac and is hypothetical. In both, the 22-ohm resistors help eliminate hum modulation and hash as well as furnishing protection for the diodes.

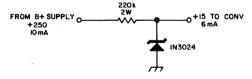

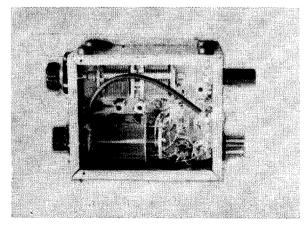

Fig. 6. You can get power for the converter from your receiver B+ supply. Important: the resistor is 22 k, not 220 k!

C2 unshorted the current could be changed from 1 to 2.2 mA by tuning the preselector around. When working, the preselector tuned 1 MHz above the oscillator gave me 1.7 mA, while tuning to the low side dropped the current to about 1.4 mA. The big variations were when the preselector was tuned only a few hundred kilohertz either side of oscillator frequency. 1 judged that bias and injection were about right.

I used a 10-µF tantalum bypass on the source resistor, on the theory that it would reduce crossmodulation if any were going to take place, but any value over a 0.1µF should work. I had a lot of the small tantalums on hand.

Tuneup: The oscillator section should be got going first, as it is used in setting up the mixer bias as above. The preselector circuits then should be made to track over the range desired. If a dual 140-pF capacitor is used, the tuning range can be about two to one in frequency; for more range, use a larger capacitor. Many of the commercial ham-band-only receivers have a similar scheme. (They cannot track the preselector with the if tuning because sometimes they are going in different directions!) No rf stage is used because of the gain provided by the UHF converter ahead, but the two coils are loosely coupled by being side by side (0.875 in or 2.215 cm center to center) with windings in the same direction and the top end of each coil hot. (With this polarity, a little capacitance coupling will add to the inductive coupling.) The two circuits have to tune the right range (or a little bit more, but no less) and should do it together, but they don't have to track with a dial or an oscillator.

I started with the slugs all the way out and went to minimum capacitance on the gang capacitor. Then using the trimmers, I put both coils at about 20 mHz. A piece of drill rod in the coil *not* being grid-dipped keeps things simple. Dip one, shift drill rod, dip other. Then to low end (11.5 mHz) and maximum capacitance put slugs where they need to be. Then, using signals from an antenna or from the dipper, you can peak the trimmers on a signal at the high end and peak the iron slugs on a low end signal once or twice and the job is done. The preselector action should be very obvious. Write down a few dial readings so you can hit them again in a hurry.

The idea is pretty much the same as

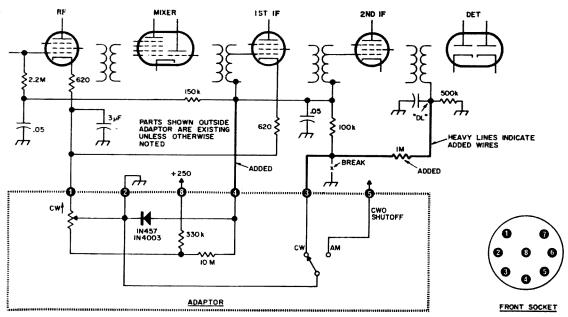

Fig. 7. Adding AGC and gain controls to the SCR-274N. The potentiometer is an Ohmite CB-2531, IRC-CTS Q14-120, Mallory U-28, RV4NAYSD253F or E. It has 25 k Ω total with about 2500 ohms to CW terminal at 50% rotation. The voltage on CCW terminal is low at low gain settings and about \pm 15 volts with the control more than half on. This means no ACG developed until -2 volts on DL. Putting the switch in the CW position puts things back to the original 274-N status. You have to use some ACG delay or there's not enough audio. Replace the antenna connector with a BNC or phono jack for converter use.

K1Q1M's "Crystal-Controlled Front End" in the February 66 issue, except that we don't use tubes. One word of caution: although I put the crystals outside the box (in sockets) I found that there was pickup from my rather local TV stations, curable by putting a shield over them. Therefore, I suggest putting the crystals inside the box. The input is a two-stage bandpass filter, the output is a low-pass filter (cuts off a bit over 3 mHz) and there is not any excuse for hash from TV signals, nor for TVI from the oscillator, if things are laid out correctly, and the power leads filtered.

Because the power drain is only about 5 mA, the juice could be stolen from the B-supply in many cases. (Be sure the regulator diode used is dependable!) The power supplies shown will work on twelve or twenty-four-volt filament windings. Without readjustment, it should be ok to use with any receiver tuning either the broadcast band or up to 3 mHz, for instance the 1.5 to 3 mHz Arc-5.

Later tests show that the \$1 Motorola MPF105 FET works very well in this circuit.

WIOOP

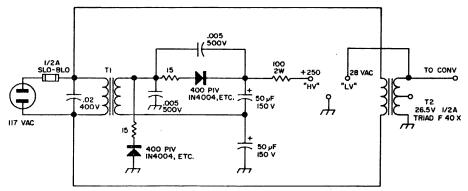

Fig. 8. Simple conversion power supply. T1 is a Lafayette isolation transformer XF or Triad N-51X (20 VA isolation transformer). Use the Triad back-

wards to keep B+ down. The 0.005 μ F capacitors and 15 ohm (not critical) resistors reduce hash in the BC band.

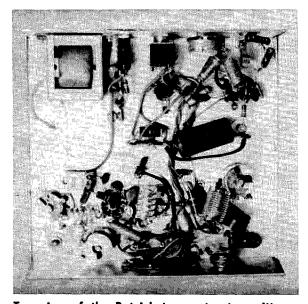

The Ratnick Twoer, Mark IV

A very simple two meter transmitter for local contacts

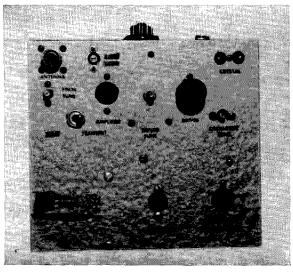

The Ratnick Twoer Mark IV is a simple two meter transmitter capable of a good signal with modulation percentage closely approaching 100%. As VHF transmitters go it is easy to duplicate. The circuit is straight forward and little trouble should be encountered as long as good VHF construction techniques are used. All rf carrying leads should be as short as humanly possible. The rule for bypassing is as follows: if you can't see the leads from the bypass capacitor you may consider it well bypassed. The lead arrangement of the audio section is not critical and any arrangement that appeals to the builder may be used.

The crystal oscillator is an electroncoupled type that oscillates on 8 MHz and has its output tuned to the third harmonic. It is very stable and may be driven by almost any high impedance VFO. The 24-MHz energy is tripled to 72 MHz in the second half of the 6U8. The final amplifier is a 5763 that doubles to 144 MHz. While this does not provide good efficiency it does simplify matters greatly in that the final does not have to be neutralized. The output is in the area of two watts and it is suggested that a high Q filter be employed in the output circuit to prevent the transfer of the spurious energy, i.e. TVI. Provision is made to key the final for CW though exceptional care should be taken to properly bypass the keyed cathode.

V3A and V3B are voltage amplifiers which are in turn fed into the 6AQ5 power amplifier. A neon indicator is used to show

Top view of the Ratnick two meter transmitter.

Bottom of the Ratnick two meter transmitter.

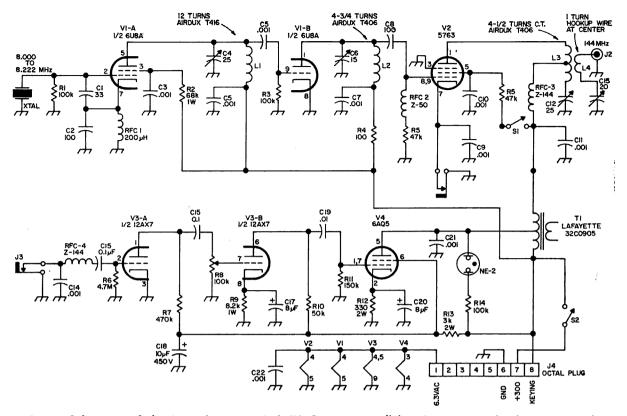

Fig. 1. Schematic of the Ratnick Twoer Mark IV. S2 is in parallel with an external relay connected to the "Keying" terminal.

the operator if he is modulating properly. If the exact values given for the tuned circuits are used no trouble should be encountered at all. The tuned circuits will just cover the frequency range needed and it should not be possible to tune them to the wrong harmonic. However, it would be wise to double check this with a grid dip meter. Insert a crystal in the socket and connect a dummy load to the transmitter through an SWR bridge. Simply tune for maximum output-it will be impossible to exceed the maximum plate dissipation of the tubes. Again double check the output of each stage with the dipper. Next plug in a microphone and slowly increase the audio gain control until the neon stays brightly lit as you talk. You will find that you have plenty of audio gain to spare. You are now ready to operate.

Results with this little peanut whistle (2 watts out) have been very gratifying and exciting. I have worked stations who said that when my signal approached the noise level the audio was still readable. While this rig is designed primarily for local ragchewing and nets it can give you quite a thrill DX'ing. With an eight element beam

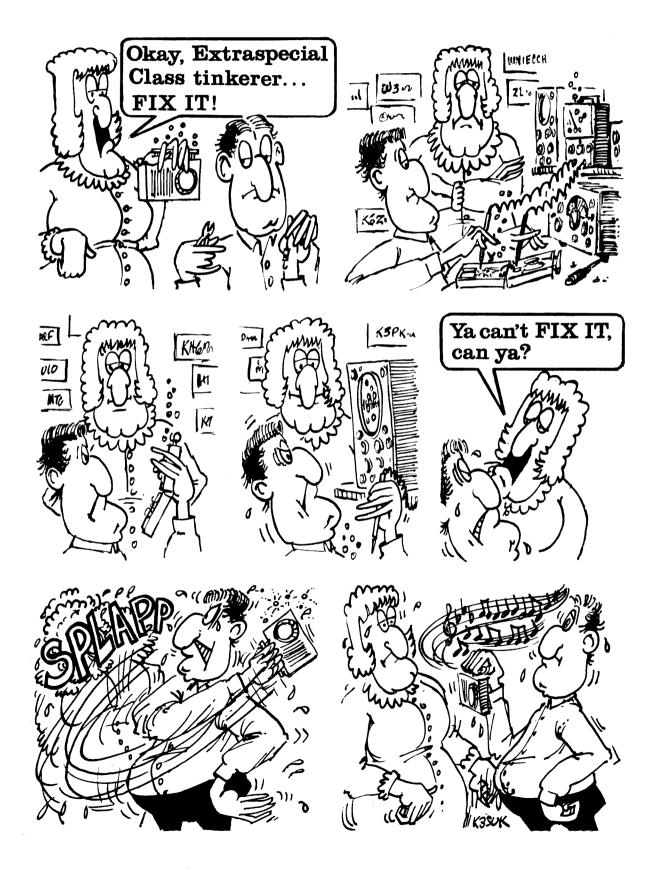

and a slight band opening I have worked New Hampshire, Massachusetts, Pennsylvania, Delaware, and Maryland without really trying and with crystal control. I also work the Windblowers in less time than many hundred watt boys. CW is also a thrill. One evening when the band was closed and no one was working anything I worked Chichester, N. H. with 5/1/9 signals. Not very strong but he was only 5/3/9 with his 400 watts. So, here's wishing you good luck and I'll see you on low power on two.

QSL cards from stations worked with the Ratnick transmitter and 829 linear from the Bronx.

The CLINIC

Cardboarding--

An integrated system to record, develop, test, index and file ideas.

Do not read this if you are in a hurry because:

It could change your attitude toward the creative phase of electronics.

Consistent application of several rules could change your way of life. The rules are valid whether your interest is vocational or advocational.

You will be induced into exploring the most obscure recesses of your mind.

The man that has not mastered his mind is the master of nothing.

If you do not have an hour to study now, put this aside until you are ready but, as a reminder write in the palm of your hand with a ball point pen the word—CARD-BOARD.

Cardboarding is a hybrid system developed from several ideas related to bread-boarding.

The genesis of breadboarding is not clear. The term has earned a permanent place in the language of electronics.

Breadboarding is used to denote mock-up, dummy set-up, cut and try engineering, or any trial layout of a temporary nature. I have seen the term used in a paper on chemistry. A physicist told ne that he had seen the term used in nuclear physics. This is understandable because the first cyclotron was a converted wireless arc transmitter from Palo Alto, California.

Early application of the term, breadboarding, was literal. Wireless components were fastened to a bread, or cutting board, to insure some physical stability and order. This method provided good access for alterations and maintenance. The flat layout on a single plane provided the designer with a bird's-eye view. A breadboard made it possible to establish a link between the abstract mental process and the concrete physical work. Oftentimes a breadboarded circuit became a permanent fixture. Large telegraph repeater stations would use huge mahogany or cherrywood tables, complemented by lacquered brass fittings, to mount the components for hundreds of telegraph channels. Some of these handsome components are conversation pieces in homes today.

I suspect breadboarding evolved from the old manual telegraph practice of mounting components on the operator's table top. As the station prospered, the tables were needed for other purposes. The components were rearranged on boards and fastened to the wall.

Various illustrations, of Alexander Graham Bell's development work on the telephone, have that breadboard look. Mr. Bell was trying to develop a multi-channel voice frequency telegraph system, nearly a century ago, when he observed a bit of phenomanae that led directly to the development of the telephone.

Mr. Bell jotted down spontaneous ideas and observations on scraps of paper, on the backs of household bills or in a small notebook. A scribbled notation related to "undulating currents" is credited with winning the patent rights to the telephone. The notation was on the back of a household bill! This incident serves to emphasize the cardinal rule of cardboarding; Record the idea or observation now.

Breadboarding

The most ingenious, fastest breadboarding I have seen utilized 'glass-knob' thumbtacks. The components are equipped with pigtails before mounting on the breadboard. The wire pigtails terminate in small loops. Several pigtails are thumbtacked together

on the breadboard to form a solderless tie point. Some of these boards look awful hairy but they are simple and easily constructed. The glass-knob thumbtack method is still practical for low frequency projects.

Commercial breadboard kits

To maintain a smooth stream of consciousness during the creative phase, breadboard designs were improved to permit the physical work keep pace with the mind. This important factor has produced a variety of systems. Several commercial kits furnish patch cords, plug-in components and special boards. The boards may be wood, plastic or metal. The more economical and simpler kits use perforated phenolic panels and special clip or spring connectors for a solder-less tie point.

The makers of commercial boards emphasize saving time (speed), reusable components (economy), and structural visualization (spacial view). These systems do not integrate the schematic diagram to improve electrical visualization. Nor a means for recording, filing, indexing and duplicating the tests. The initial expense of the more elaborate kit is a disadvantage to economy minded experimenters. An elaborate kit, due to completeness, quality and flexibility is inherently costly. There are other features the experimeter may consider to be of greater importance. It is necessary to analyze the creative mind to illustrate that last statement.

The creative mind

All men are creative.

No race has a monopoly on invention.

All forms of mankind have contributed to the state of civilization that exists today. The ability to rationalize, to exercise logic and to project, are talents that distinguish mankind from animals. Another way of putting it; Man can prophesy. Current events seem to belie this, nevertheless, it is a fact. It is also true that mankind cannot predict every event in the future, however, the number of things mankind can predict exceeds the capacity to assimilate by any one man.

The creative talent varies among individuals. There are many factors that make up this talent. Some factors are inherited and others are the product of our environment. Most of these factors can be acquired

by self study and self discipline. Here is a list of the predominant ones; Motivation, Education, Opportunity, Reinforcement, and Serendipity.

Motivation: Motivation can be generated by the desire to serve and is the noblest of mankind's endeavors. The will to survive, which is inherent in all normal men. Curiosity will stimulate a man into doing all sorts of curious things. There are others not so noble but powerful such as prestige, power, money and greed.

Education: The sum of all your knowledge composed of experience, environment, academic or self-trained at least in the area of interest.

Opportunity: Opportunity is related and proportional to your education. The broadest education possible is the best insurance that you will be exposed to opportunities.

Curiosity: Curiosity is considered an inherent trait. This valuable trait can be developed and parallels education. Curiosity can lead you to bold origonal concepts.

Reinforcement: This factor is a concrete form of encouragement. A series of minor successes or rewards will sustain a man for many years on a single project. For the competitive man success, based soley on 'being a winner', will suffice to make him expend enormous amounts of energy.

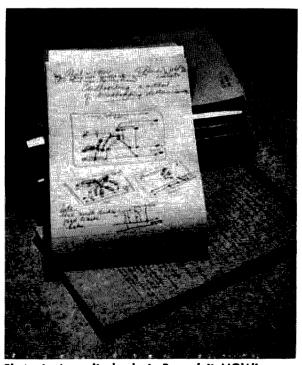

Photo I. A cardinal rule is Record it NOWI

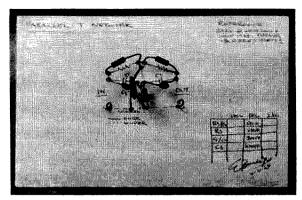

Photo 2. Groups of pinholes form tie points.

Screndipity: This is probably the least discussed but one of the most valuable traits a man can acquire. An artist would define serendipity in this manner; Use whatever means and materials you possess to create a thing of beauty. A prosaic man would simply state; Improvise.

Ideaphoria: This an obsecure word rarely found in dictionaries. Ideaphoria is the rate or volume of creative ideas. The word is used in aptitude test results. A high ideaphoria indicates a highly creative imagination in the individual. In the context of this paper I am using the phrase 'creative mind' to connote high ideaphoria. The creative mind is a fulcrum upon whose sharp edge is balanced a man's sanity. Should his other talents be properly distributed he will be a prolific producer. He will be using all his talents and enjoying peace of mind. If the individual has not inherited or developed the other talents, he will become a paralyzed egomaniac who could destroy himself through utter frustration.

The preceding paragraph parallels my experience which led to the development of cardboarding.

The creative mind does not conveniently have single ideas.

The creative mind is boiling with ideas. It must improve everything it observes. Ideas pop out like olive pits. Most of these ideas are lost in the confusion and stress of the moment. The secret of capitalizing on the creative mind lies in some means for capturing these transients. These means must provide a favorable gestation period where the ideas can be selected or rejected in a stable environment. The resultant effect is to immobilize your ideas so that they may be examined and re-examined when the

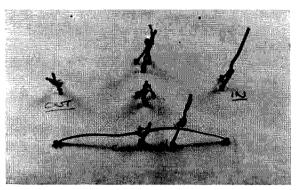

Photo 3. The pigtails are tacked together on the wiring side and lock the components to the card-board.

time and the attitude is right. The creative mind is capable of exploring many projects concurrently, with a little help. This discussion on the creative mind has led us, full circle, back to breadboarding.

In order to accent more desireable features that should be incorporated in the bread-boarding process, a lengthy digression on the creative mind was presented. At least one of these features should be obvious. Perhaps it will help if this rhetorical question is asked: Can you imagine how much money an experimenter would have to invest in a breadboard system that could handle a half dozen projects simultaneously?

The cardboarding system includes this feature, with considerable economy.

The great ones

Men who have contributed much to our technology and comfort were not men with one track minds. Study the biography of any one of these men; Franklin, Jefferson, Whitney, Tesla, Bell, Edison, deForest, Armstrong, Steinmetz and Lawrence. The names are usually identified with one great contribution. This great contribution was the pinnacle of their endeavors. It is a rare pinnacle with a broad base. All these men had creative minds, not one idea in one field but prolific in many fields. The key to their genius reveals itself, not in a formal textbook presentation, but in scribbled notes, crude sketches on scraps of paper and little dog-eared notebooks.

It is true, conception is rarely neat.

These great minds, the orderly scientist, the prolific inventor and the great innovators, how could they generate a shining image of order and enlightment when all that

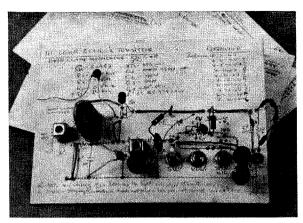

Photo 4. Jumpers interconnect the tie points either above or below.

can be found of the beginnings are scribbled notes and crude sketches? The answer to this question is the key to their genius.

Even though you scratch a word in the dust, it will be engraved forever in your memory.

Another way of putting it; It matters not the place nor time, nor why nor how. It does matter by rote or rhyme, record it now.

The cardboarding system

The cardboard feature of this system was one of many ideas recorded over a decade. The cardboard idea became the catalyst that bound several related ideas together to form an integrated system.

Cardboarding begins when you record the idea. (Photo I) The cardboard feature parallels the stream of consciousness during the development and testing phase. The system provides a record of progress and summaries. A method for filing the cardboard is provided. The information is crossindexed, retrievable and reproductable on the original cardboard. This list and illustrations explain each step applied in sequence.

1. Recording the idea:

The transient idea must be recorded immediately. This requires an ordinary pencil tablet (10c). The 5½x9 inch size with the least number of pages will insure that enough room is available on the back cover for indexing. Over a period of years the number of tablets you fill with ideas will amaze you. Use the most available to maintain some uniformity for storage. The front cover should carry the date of the first entry, when the last entry is made add it to the front cover. These two dates will give you random access to the correct notebook.

A clean page is devoted to the idea, no matter how incomplete the idea may be. A simple basic drawing and explanation is sufficient. The date, title or keyword and your signature is recorded at top of page. These items are then entered on the back cover, and is the beginning of the chronological index to provide random access to contents of the notebook. Subsequent entries are made chronologically on clean pages, the date and title is followed by word or words keyed to the change or modification. This is also transferred to the back cover.

When a cardboard is started: The original date, title from your notebook and signature is placed near the top edge. The starting date of the physical work on the cardboard is added on the date you actually begin. In some other area, either front or back, of the cardboard enter all previous and subsequent dates and keywords in chronological order. Include source or reference articles from books and magazines. As development progresses, continue recording on clean pages of notebook, index cover and the chronological list on the cardboard. This description appears to be complex. In practice it is simple because it follows a natural flow of activity and is a chronicle of that activity. If you adhere to this discipline, you will have a cross-indexed record that is nearly fool proof. Experience has revealed that time spent on records is small compared to the time spent on the whole project.

2. Cardboarding the idea:

- (a) Cardboard stock—ordinary file cards are too light for all but the simplest circuits. Posterboard will handle everything except the heaviest components such as large power transformers. Posterboard is supplied in 22"X28" stock by stationary and art supply stores.
- (b) Cutting stock—household scissors will cut the heaviest stock you will ever use. Illustrations show 5"X8" cards of various weights. Think small, 3"X5" think big, 8½"X11".
- (c) Schematic drawing—arrange components so the drawing will form groups of tie points and still maintain a readable schematic. (Photo 2) The tie points are a group of several pin-holes. They are spaced about \(^{3}\)/₁₆" apart. This allows the pigtails to pass through the cardboard separately to merge underneath or wiring side.

The ends are tacked together with solder. This method provides a locking feature for small self supporting components such as resistors, capacitors, transistors and diodes. A jumper wire on either side of cardboard can interconnect tie points. The schematic will be easier to read if components are properly spaced. Study photos 3 and 4. A simple bridged-T filter pad requires a minimum of interconnecting jumpers. The other extreme is illustrated by a cardboard of shielded inductors, switches, jack, potentiometer, crystal holder and transistor. Fortunately the components tend to stiffen the cardboard.

(d) Making the holes-Pinholes are made by a needle-chuck test prod. The larger holes, %" to %6", are made by burning, with a modified Ungar type burning kit. Woodburning kits are available in toy or hobby shops. The largest tip is stepped down to four sizes by a small lathe or bu chucking in an electric drill. (Photo 6.) The electric drill is clamped in a vise. The tip is filed down while the drill is running. Diameters between steps is not so important as maintaining a square shoulder between between steps. A flat face at each step will insure clean holes. Holes may be enlarged by wiping hot tip around inside of hole. (Photo 5). Extremely large holes are made by chassis punches. Burn holes can be cleaned with an old toothbrush. A small jar, with %" hole in lid, is an anvil. The cardboard is placed over hole of anvil for punching or burning. Anvil will catch any debris from burning and brushing. All the tools are stored in the filebox. Photo 7 of the file box shows all tools used in the cardboarding system.

(e) Recording changes: As development progresses record important modifications in the notebook with suitable index on back

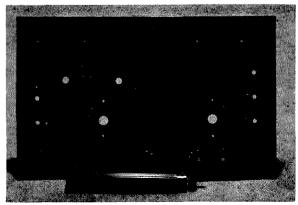

Photo 5. The large holes are burned in.

cover. The date and keyword is added to cardboard to maintain cross-index feature. When you reach a stage of development where you want to record progress, summarize in the notebook, and complete the cross-indexing routine again.

(f) Termination of development: When the project has been explored to a point where no further progress is anticipated, or development work is complete, the components are removed from cardboard and put back into stock. The final entry in the notebook should be summary with appropriate conclusions. The cross indexing procedure is applied to cover and cardboard again, before filing the cardboard.

3. Filing the cardboards:

File boxes are available in several colors. materials and sizes. Prices vary from 50c to several dollars. The file box shown in the photograph is 5"X8", of metal and finished light gray. It has a full length piano hinge and is of excellent quality. The retail price with indexed separators is less than two dollars. The boxes found in variety stores are of lesser quality and retail for less than a dollar. The larger boxes, 8½"X11". complete with separators and lock can be bought for less than two dollars. The use of an appropriate title for the project simplifies filing and access. If you can remember only one date of several that relate to the project, or the title of project, you can recover all the information on the project in a few moments.

4. Conclusion:

To insure successful operation of this system these rules must be practiced religiously;

(a) Get that spark of inspiration recorded, even though you write on the palm of your hand with a ball point pen!

(b) Paradoxically, the act of writing improves your memory.

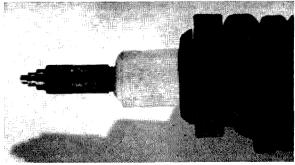

Photo 6. Maintain a flat face at each step on the modified tip.

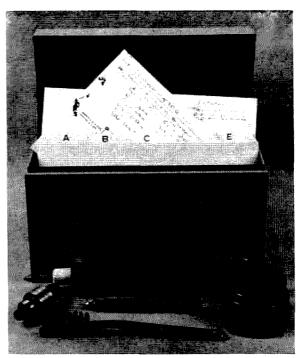

Photo 7. All the tools can be stored in the file case. The anvil was made from a discarded D-72 chemical developer jar. The hole in the top was made by the socket punch shown at the left.

- (c) Maintain the relationship between notebook, cover index and cardboard entries.
- (d) Use jumpers between tie points on the cardboard.
- (e) Plan the cardboard drawing to look like a schematic.
- (f) Before burning holes, brief your family because they may run around the house sniffing smoke.

(g) Continuous application of these rules will develop automatic reflex action.

Cardboarding should prove useful at all levels of research and development. Cardboarding could serve education in technical schools by using basic schematics, printed in quantity with prepunched holes, and distributed to the students. As part of the course every student should be required to maintain his own notebook, cardboards and file box. The system remains his property and becomes the foundation for building a solid background in electronics. This system will help the student to understand the working of the mind and develop professional discipline.

A youngster trying to master the basics of electronics through this system might be the man to put us on Mars or, eliminate us from the Solar system. Who knows?

Buried Antennas for Emergency Communications

In this article, WIDCG describes some of the properties of buried antennas, particularly in relation to their usefulness for amateur Civil Defense or other emergency communications installations.

Many experiments have been conducted with sub-surface antennas in recent years to allow construction of bomb-proof communication sites and for communication with deeply submerged submarines.

Some scientists believe in the possibility of a super-conductive medium in the earth's crust so that antennas could be buried in the ground in an upsidedown fashion and communications established using this "earth ionosphere" much the same as surface antennas work in conjunction with the ionosphere.

However, experiments in this field have not been very successful and a buried antenna, for practical purposes, can be treated as having useful propagation only above the surface. The deeper the antenna is buried, the more inefficient it becomes because of the earth's absorption of the radiated energy.

What application do such antennas have for the amateur? Few amateurs are faced

with such a drastic situation that they can't put up some form of surface antenna, even if only attic antenna for short whip. However, for those engaged in Civil Defense or other emergency communications work, the installation of a buried, "back-up" antenna at a fixed station should be considered. It is quite a contradiction to see so many times an emergency communications setup in a relatively protected area—the basement of some public building, for instance—and then to see the antennas on which the usefulness of the installation entirely depends, dangling loosely in the open liable to any extreme surface condition, natural or man-made.

The purpose of this article is to review some of the types of buried antennas which might be useful for amateur emergency communications and to present some of the results the author obtained with a buried 40 meter antenna.

SURFACE INSULATED WIRE (A)

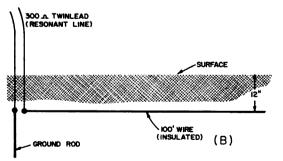

Fig. 1. The dipole (A) and 100 ft. long wire types of buried antennas. Constructional details are given in the text.

Buried antenna properties

Because a buried antenna is immersed in a very lossy medium and because of the sudden difference in medium which, a radiated wave encounters at the interface of earth and air, a number of factors are drastically different for buried antennas as compared to an antenna in air.

Because of the antenna being in a different medium, the length/impedance versus frequency characteristics are different. For instance, a simple dipole buried 1' in soil of moderate conductivity would be about 17½' long for 20 meters and have a center impedance of about 450 ohms. As may be imagined, these figures are very dependent upon the exact conductivity of the soil.

Because of the interface between earth and air, the radiation from a horizontal, buried antenna when it reaches the surface sets up a vertically-polarized ground wave. This factor, of course, is ideal for emergency com-

munications work with vertically-polarized mobile stations.

Antenna forms

Many different forms have been tried for buried antennas and even complex directive arrays have been constructed. However, for amateur purposes, the dipole and 100' long wire are probably the most useful forms. (Fig. 1.)

The formula for the length of a dipole depends upon ground conductivity as well as other factors and would not be of much use to the average amateur. The best procedure for constructing a dipole is simply to cut it to 80% of the free-space length and then trim the ends equally until the lowest SWR is achieved. If buried in an area where ground conditions remain stable, the length does not have to be changed again.

In areas where ground conditions and surface conditions (snow, extreme changes of vegetation) are not stable, the 100' long wire should be used. Although an antenna coupler, such as a transmatch, is required to allow compensating for impedance changes with varying ground conditions, the antenna can then also be used for multiband operation. In typical soil the input resistance of such an antenna will vary from 50 to 600 ohms and the reactance from ± j400 ohms over the 2-20 MHz range. The first resonance will be between 750 and 1800 kHz, which makes it effective from 80 meters on down. This type of antenna has been used by the Army in Viet Nam with good results over short tactical distances.

Construction

Whether a dipole or 100' long wire is used, the wire used for construction must be insulated along its length from the soil and care must be taken that moisture does not penetrate the tips of the wire or the connection to the feed line. Teflon insulated wire, numbers 22 to 26, is particularly suitable. Perhaps a less expensive method is to run plain rubber insulated wire inside plastic hosing. The ground connection for the 100' long wire can be a standard 4 or 5' TV type ground rod.

Efficiency

Many methods have been used for measuring the efficiency of buried antennas. Per-

haps the most realistic for amateur purposes is to compare the field strength from a buried antenna to a good, surface quarter-wave vertical. Experiments made on this basis have showed buried antennas of the dipole and 100' long-wire variety, when compared to a surface antenna resonant at the same frequency, to be about 40 db down for a burial depth of 1'. Roughly, this is about twice the order of magnitude reduction in signal strength as would take place between a 8' loaded 80 meter whip and a full-size quarter-wave 80 meter vertical.

Experimental results

The author constructed a 100' long-wire buried about 8" and operated on 40 meters. No impedance measurements were made but proper loading could be easily achieved with the use of a transmatch-type coupler, although some retuning was necessary periodically depending on whether the soil surface was moist or dry.

No surface, vertical 40 meter antenna was available to make signal comparisons but comparisons were made with a 40 meter dipole elevated about 40 feet. On local and short-skip contacts, the buried antenna was never better than 7 "S" units below the dipole with the average being around 8-9 "S" units.

Conclusion

Buried antennas still offer many possibilities for experimentation. The main caution to observe is that the length, impedance and other parameters of surface antennas cannot be used.

Buried antennas are terribly inefficient as compared to almost any type of surface antenna except perhaps extremely short, unloaded whips. But, for emergency communications installations, they do offer the possibility of having a standby antenna which is easily installed and which can be pre-tuned and immediately available for use should something happen to the installation's primary antenna.

W1DCG

For those who would like further detailed, engineering data on buried antennas, the following compilation of articles is extremely useful: IEEE Transactions, Vol. AP-11, May, 1963. Special Issue on Electromagnetic Waves in the Earth. IEEE, Box A, Lenox Hill, New York 21, New York.

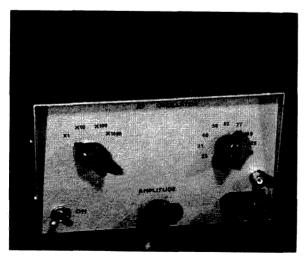

A Transistor Wien Bridge Oscillator

In this article, W6GXN discusses the evolution of a Wien Bridge audio oscillator that generates 25-200,000 Hz sine waves with very low distortion.

Virtually every audio oscillator, that the author has ever seen in laboratory use, is of a type called the Wien Bridge. This type of oscillator is characterized by a particular configuration of R-C tuning network. The original circuit of the Wien Bridge Oscillator is shown in Fig. 1, as it was first constructed using vacuum tubes.

In Fig. 1, the two stage circuit sustains oscillations because of the phase-shift of the bridge (at a particular frequency) and the phase shifts of the two amplifiers (assumed constant over the frequency range of interest). Such an RC oscillator would produce a highly nonlinear waveform (like that of another R-C oscillator, the astable multivibrator), if it were not for the nonlinear resistance "r". The resistance r is variously called a positive-temperature-coefficient thermistor, a barretter, or a light bulb.

When the circuit of Fig. 1 is in its desired state, the tubes are running in class A, and

Front view of W6GXN's Wien Bridge audio oscillator.

the output is sinusoidal. A change in operating state toward class C (which would produce a much larger output of highly distorted waveforms) causes more current to flow in the Ra-r side of the bridge. This increases the temperature of the light bulb (r), which causes its resistance to rise. The increase in resistance of r causes the gain of the amplifier stage V₁ to decrease, which restores our original operating level.

To see how the lamp resistance varies with current, Fig. 2 depicts a (commonly used) 6 watts 120 V lamp E-I plot, with several lines of constant resistance drawn in for reference. The translation of the tube-type Wien Bridge circuit into a transistorized version has had many problems, and the solution of these problems has been so complicated that the basic simplicity of the Wien Bridge oscillator often has been lost. In many a transistorized Wien Bridge audio oscillator, when the problem areas have been designed around, the resultant circuit hardly resembles the original Wien Bridge at all. This is not bad, per se, and several good Wien Bridge audio oscillator designs have come forth using bipolar transistors. 1,2

Basically, the reason that the Wien Bridge oscillators using bipolar transistors are so hard to build is that ordinary transistors have a relatively low input impedance in the common emitter configuration.

In Fig. 3, we see a hypothetical Wien Bridge oscillator using bipolar transistors. Since the input impedance from base to ground is fairly low (approximately hrexf), this low impedance shunts R₂ and upsets the requirement that R₁ = R₂. Also, since hrexr is amplitude sensitive, frequency will be dependent on amplitude. These two problems generally force the designer to:

1. Use low values of R₁ and R₂, together with large values of C₁ and C₂. This means that resistance tuning *must* be employed.

Use some other negative feedback method for controlling amplitude, rather than
the simple lamp-in-the-emitter method.
Negative temperature coefficient thermistors and forward-biased diodes are two of
the nonlinear elements used for this.

With the advent of field effect transistors, the design of simple solid-state Wien Bridge oscillators came within easy reach. The FET has an inherently high input impedance in the common source configuration. However, most of the designs that the author has seen using an FET as the input amplifier, have not used the same sort of lamp amplitude control as used in the older tube-type circuits.^{3,4,5}

The circuits below were redesigned from the old vacuum tube Wien Bridge circuits, for simplicity and ease of understanding. The first attempt, Fig. 4, used the same type light bulbs as do many of the tube type oscillators,

and also used capacitive tuning.

The circuit of Fig. 4 used one of the relatively new insulated gate FET's, the RCA 3N98. With a maximum design-capacitance in each section of the variable capacitor of 500 pF, at the minimum operating frequency, very high resistances (many megohms) were required for R₁ and R₂. At such a high impedance level, the circuit readily picked up 60-Hz ripple, and it was quite essential that it be enclosed in a shielded cabinent.

The bridge-sensing amplifier was the only FET in the circuit, since this was the only place where one was needed. A conventional bipolar voltage amplifier Q_2 and a complimentary emitter-follower completed the oscillator. The emitter-follower was used to provide a low output impedance. The circuit was powered by a separate +28 volt regulated and +28 volt regulated and +28 volt regulated and +28 volt regulated +28 volt regulated +28 volt regulated +28 volt regulated +28 volt +28

lated supply.

Since the main frame of the dual variable capacitor was the common terminal, which was connected to the gate of Q₁, one would expect a fairly large stray capacitance to ground in shunt with C₂. This had to be equalized by a trimmer (C₃) across C₁ if oscillation was to be maintained near minimum C settings of the dual variable. Also, of course, an insulated (ceramic) shaft coupling had to be used on the variable capacitor shaft and the capacitor frame had to be supported by ceramic or high-quality plastic insulators. C₄ and C₅, in parallel with C₁ and

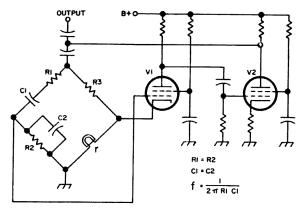

Fig. 1. Typical tube-type Wien Bridge audio oscillator.

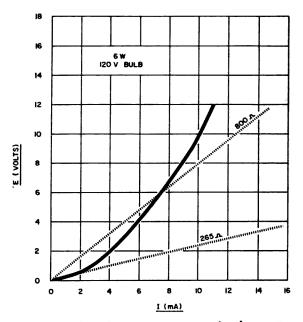

Fig. 2. E-1 plot of a 6 W, 120 V pilot lamp. Two constant resistance load lines are also shown for reference.

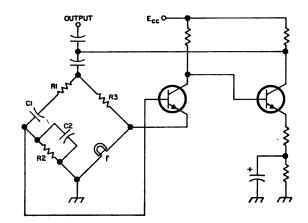

Fig. 3. Theoretical transistor version of the Wien Bridge shown in Fig. 1. Unfortunately, this simple adaptation isn't satisfactory because the low input impedance of the first transistor appears in parallel with R2 and loads it too much.

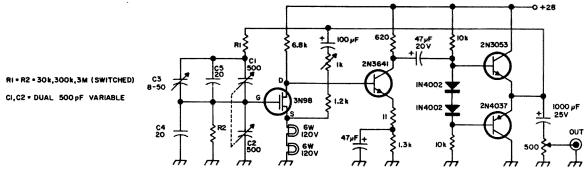

Fig. 4. First version of a moderately successful Wien Bridge oscillator. For low frequencies, RI and R2 have to be so large that the circuit is very susceptible to noise and hum.

C₂ were simply to fix the minimum tuning capacitance.

The design worked quite well in the ranges above 100 Hz, but the lowermost range (10 Hz to 100 Hz), where the required resistance values were 30 megohms, was unreliable, as feared. At this point, capacitive tuning was abandoned in favor of a combination of capacitor and resistor switching.

The second and more successful Wien Bridge audio oscillator was built using a junction FET. By switching both R and C, bridge component values are more manageable (and available). The C values in this second version are $0.52~\mu\text{F}$ to 500~pF, and the R values are between $100~\Omega$ and $3300~\Omega$. Fig. 5 shows the circuit of the oscillator; it is very similar to Fig. 4. The feedback control element used here is a Sylvania 120 MB lamp for which a typical E-I curve is shown in Fig. 6. Note that this lamp allows us to

use a single bulb to operate at a source resistance of about 600 Ω . Also, the Sylvania 120 MB is physically smaller than most 120 V bulbs and fits a small bayonet pilot lamp socket, like that for a #47 or NE51. The lamp is available from Allied Radio for \$0.46. The oscillator is constructed in a LMB-WIA cabinet, as shown in the photos.

The capacitors are switched only each decade, and the resistors are switched in ten increments between decades. The seemingly-nonsensical increments of frequency were chosen to give points that are approximately evenly-spaced on semilog graph paper—the type of paper usually used when plotting the frequency response of an audio amplifier. The four pairs of capacitors were "built-up" starting with 0.47 μ F, 0.047 μ F, 0.0047 μ F, and 470 pF capacitors, by adding small capacitors in parallel; a bridge was used. The resistors were all 1% tolerance types from

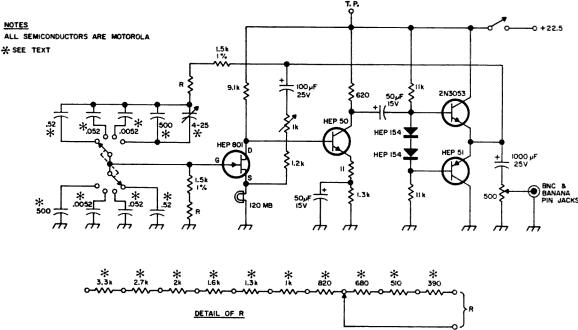

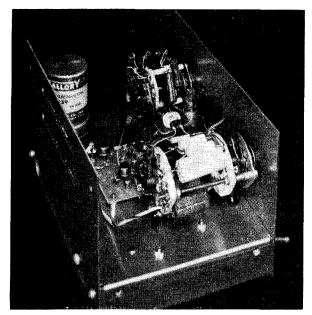

Fig. 5. The most satisfactory version of the Wien Bridge oscillator. This circuit is used in the oscillator shown in the photos.

Interior of W6GXN's audio oscillator.

a local surplus emporium; Their marked values were trusted.

As in the first oscillator, a small trimmer capacitor was placed in parallel with the C in the series arm of the bridge to make up for stray capacitance to ground (and the input capacitance of the FET.) This trimmer was not necessary except on the high range, where 500 pF capacitors were used.

A burgess U15, 22½ volt, battery was used to power the oscillator. It is mounted under the chassis in an Austin #113 battery clip. In this mounting configuration, the battery cannot damage the circuit board if it leaks. A test point is provided on the rear of the cabinet to test the battery voltage under load.

A quick check at 1000 Hz revealed that second harmonic content of the waveform was 48 dB below the fundamental. Higher harmonic content was greater than 50 dB down, with the even harmonics being the

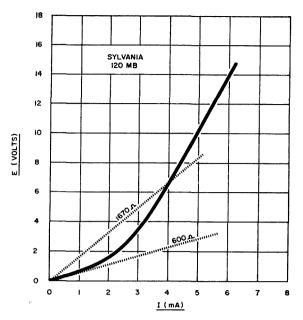

Fig. 6. E-1 plot of the Sylvanis 120-MB pilot lamp.

strongest. The output amplitude was within 1 dB across the entire frequency range.

The author wishes to thank Gene Howell, WB6JOV, for the photographs of the audio oscillator.

Proof Positive

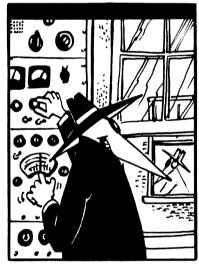

Have you ever found yourself with a fine project to build, and then discovered that you have all the components on hand but the rf chokes used in the circuit? Perhaps you've wondered if any of the chokes you have in your junk box will work. Well, here's a way to find out. It's an old idea, but a good one. The only equipment you need is a grid dip meter. Set the GDO to the frequency of the part of the circuit in which

you are going to use the choke. Then select a junk box choke that looks like it might work, and, holding one lead, touch the other to one of the exposed pins on the grid dipper coil. There will likely be a change in the GDO meter reading. The greater the change, the poorer the choke will work at the selected frequency. If little or no deflection is noted, the choke will work fine at this frequency. This is a good method for testing those TV peaking coils and other chokes found in so many junked TV sets.

SORRY-ABOUT-THAT, PROHIAS DEPT.

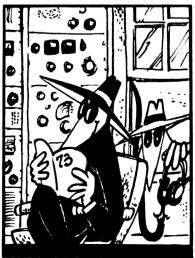

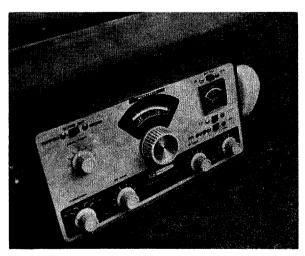

Have You Tried Air Mobile?

By some strange coincidence, the number of licensed hams roughly equals the number of licensed private and civil pilots. A guess would also suggest that the number of active stations would also approximate the number of active civilian aircraft (100,000). It also holds that there are a number of hams who are actively interested in flying. What the percentage is, I don't know. At a recent luncheon of fifty hams at the Colt's Neck Inn, six where active pilots, and at least two make it a regular practice to operate air mobiles. There must be a lot of interest, for whenever I operate from my plane, stations are always asking for detailed information on the equipment used, particularly the antenna.

I have tried many different arrangements, in different planes, with varying results. These range from meters in a luscombe in 1939 to a crystal controlled H W -12 in a Stinson from Isla Mujeres to Kew West in 1966. The results have been both good and bad. When I operated five meters in the Luscombe I used a superregenerative receiver. Since the flight (only one) was in the metropolitan New York area, everything could

Crystal-controlled HW-12 under the rear seat of the Stinson Voyager. Photo by W3PYF.

be heard (including ten meter harmonics), but with the poor selectivity of the super regenerative receiver, nothing could be copied.

In the 1950's many of us took part or heard of the work of Arthur Collins, General Butch Griswald, General Curt Lemay and others when they so effectively demonstrated to the Air Force the benefits of SSB for HF air-to-air and air-to-ground communications. For the past six years all my airborn hamming has been on SSB. Different planes and different equipment have been used but always with the same satisfying results. With the adoption of SSB and the availability of light, efficient transceivers, the utility and effectiveness of airborne ham communication has been greatly enhanced.

Our first use of a modern transceiver in a plane was with a KWM-2 in a Bellanca Cruismaster in 1960. In this case the KWM-2 was set on the rear seat, the power supply on the floor and all connections were made to a terminal plate about 3" x 12" on the lower right panel of the rear of the seat. Use of this panel avoided alternation of the plane's weight and balance. The plate had outlets for 12 V DC, Audio, and antenna. The antenna and audio used phono jacks and the 12 V DC used standard 110 V polarized female outlet. Naturally it was fused. For an antenna, there was the fixedsense antenna for the ADF which ran from the top of the cabin to the tail. It was just short of a quarter wave for 20 meters.

A switch was added over the pilot's head, which changed this antenna from the ADF to the outlet plate in the rear through a loading coil and coax. This loading coil made the antenna resonant on twenty. There were other positions on the switch which provided for operation on 40 and 75 but very little were done on these frequencies as the performance there left much to be desired. I have never had much luck from the plane

on frequencies where the antenna was not nearly resonant in itself, or where it needed a large loading coil. This arrangement was used with great success on many trips to Florida and one from Florida down through the Bahamas to Haiti, the Virgin Islands, Puerto Rico and back to West Palm Beach in February, 1962. All of the trip was on twenty meters. There was constant communication from our take-off at Stuart, Florida, heading out over the water to Great Exuma, with one stop at Grand Bahama. Communications were solid. There was a brief time after the ground wave gave up and before the sky wave came in when contacts were made with stations in the north. but at no time were we out of contact on the ham radio. In fact, when we were in sight of West End, Grand Bahama, and could not raise Palm Beach on the aircraft VHF radio, Bud Walker, W2EE/4, parked in his car in front of the Palm Beach Tower. stepped in and closed our flight plan for us after getting our request for the same on twenty meters.

This was my first experience at overwater flying in a single engine plane. As they say, the engine always goes into automatic rough when over water, and this was no exception. What a wonderful relief it was to have W4RNT and many others ready to summon help immediately if it was needed. It wasn't until after our return that I learned that Babe, W4RNT, my anchor post, could not find Georgetown, Great Exuma, on his maps spread on the floor of his shack as he followed our course. After an overnight stop at Georgetown, we left early for Port-Au-Prince, Haiti. The whole crowd was waiting for our appearance on twenty meters which kept us company constantly.

At Port-Au-Prince we were met by HH9DL who escorted us to his plantation on the north coast, near Cap Haitien. Don, HH9DL, whom we had met on twenty meters, also is a pilot. After talking to him several times on twenty meters we accidently met while we were both grounded in Salisbury, Maryland, on account of weather. He has been flying his Cessa 195 back and forth between Miami and Haiti for eight or ten years. It was his encouragement that inspired me to make this particular island hopping flight.

Don helped us clear customs, which spoke only French, then led us, in his 195 back north to the plantation, about a hundred

Alan W3ZP and his wife as they prepared for a flight to the Virgin Islands. Photo by W4RNT.

miles. It took only 45 minutes by air but would have been an all day ride over impossible roads.

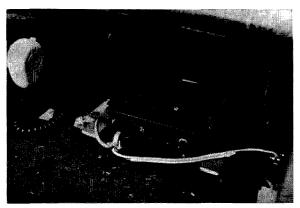

A few beautiful days were enjoyed at the plantation, where the hospitality included their Mar'd Grau. HH9GR, George Rippey, and HH9DS, Dick Smith, are also with the plantation Dauphine.

Returning to Port-Au-Prince for one night and some shopping, there was an early takeoff and over the mountains skirting the Dominican coast some 30 miles over Mona Island, Puerto Rico and landing at St. Croix, Virgin Islands. non-stop.

At no time was there any breakdown in the ham communications with any stations following our course constantly. Very comforting as, for the most part, it was our only communications.

The return trip went about the same way. To San Juan, then over water with no sight of land for some 500 miles to Great Inagua. A gas stop there and then non-stop to West Palm Beach. The ham contacts were continuous. Between Great Exuma and Nassau, we talked to, passed, but never saw, W1PRI, who was flying his Bonanza south and operating his KWM-2 on twenty meters too.

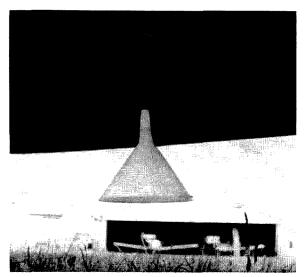

Frank Melville, W2AQK, followed us that

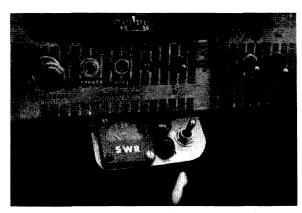

The HW-12 DC supply installed under the rear seat of the Stinson Voyager. Photo by W3PYF.

day by about an hour, but we did not see him after leaving San Juan. He had no air mobile, just a KWM-1 which he carried in his baggage. He had set it up on St. Croix. With no air mobile, he was sort of out of the club.

After that trip, and at W1PRI's suggestion, we obtained a surplus WW2 electric antenna reel, which are so plentiful. They are designed for 24V DC, but they work quite well on 12 V. They are used with a reflected power meter. Just run the antenna out till there is minimum reflected power. This is done for any frequency and provides excellent performance; - far better than the shorter antennas. Of course remember to reel in the antenna before landing or carry along a lot of spare antenna wire. We have used 40-lb. test phosphor bronze fish line successfully at 100 mph speeds, but heavier wire, with a cotton center, is necessary for the 150-200 mph speeds. A two to

Antenna and funnel hanging from the belly of the Stinson Voyager. Photo by W3PYF.

Electric antenna reel control and reflected power meter. Photo by W3PYF.

four inch plastic funnel on the end of the wire serves as an effective drag.

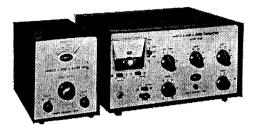

If you do make any trips with an air mobile, you will probably find that you will want some ham radio at your destination or stops. Take along an ac supply and some wire for an antenna.

Later the KWM2 was replaced with an HW-12 crystal controlled on 3999 per April 1965 QST. With the superior performance of the long antenna, distances up to 800-1200 miles can be covered consistently without the dead spots of the higher frequencies. Later this whole set-up was taken from the Bellanca and installed in a 1948 Stinson. As shown in the photos, here again everything is plug-in. Not only does it simplify conformance with the FAA regulations but it is also possible to take the HW-12 and power supply from the plane to the car in a few minutes.

In the winter of 1966 a fine trip was enjoyed in this Stinston. Starting from near home at Doylestown, Pennsylvania, one bitter cold morning, the night was spent at Memphis after stops at Cleveland, and Bowling Green, Kentucky. The next night it was Rockport, Texas. Then on around the Gulf with stops at Tampico, Vera Cruz, Ciudad Del Carmen and across the Yucatan jungle to the isle of Women, Isla Mujeres.

If you examine the radiation pattern of a horizontal antenna as given in a handbook, you will see that there is a lot of very low angle radiation from a horizontal antenna many wavelengths high. This is born out in practice from the plane. Signals on the long skip are very good. There was no problem working clear across the gulf on 3999 even during the middle of the day. The distance was as much as 1000 and 1200

NEW VFO FOR TX-62 or any other VHF TRANSMITTER

NEW AMECO VFO FOR 6. 2 & 11/4 METERS

The new Ameco VFO-621 is a companion unit designed to operate with the Ameco TX-62. It can also be used with any other commercial 6, 2, or $1\frac{1}{2}$ meter transmitter.

Because it uses a transistorized oscillator circuit, it is extremely stable. An amplifier stage provides high output at 24-26 MC. The VFO includes a built-in solid state Zener diode regulated AC power supply.

This new VFO is truly an exceptional performer at a very low price Model VFO-621 \$59.95 net.

The NEW AMECO TX-62

In response to the demand for an inexpensive compact VHF transmitter, Ameco has brought out its new 2 and 6 meter transmitter. It is easy to tune because all circuits up to the final are broadbanded. There is no other transmitter like it on the market! the market!

SPECIFICATIONS AND FEATURES
Power input to final: 75W. CW, 75W. peak

miles. I have also noticed times when I could hear and work these long distances while they could not be heard at fixed stations directly below me.

An Ac supply was carried on this Mexican trip along with a portable antenna. It came very handy on the Isle of Women. The operation there was not legal, as we had not gotten a Mexican license and there were no hams on Isla Mujeras whose calls we could borrow. Of course we were not legal flying over Mexico either. We always signed our location as south of Brownsville.

We were held up at Isla Muieras by bad weather for several days. There was no way of getting weather reports or forecasts. We particularly needed to know the windsaloft forecast for Key West in order to calculate our ability to reach Key West, 400 miles away, with the fuel we had aborad. One morning, before the weather had cleared, we had a brief contact with Art Lynch, W4DJK, in Fort Myers, Florida. All of those contacts from Isla Mujeres were brief. Our hotel room was less than 100 yards from the government radio station. Their key clicks were loud and I did not want any questions asked about the legality of

my operation. Art called the airport in Fort Myers and got a favorable wind and weather forecast. Even though the weather looked bad where we were, with rain and low clouds, we took off keeping low and under the clouds in rain. The weather did improve after we were about 200 miles out. It is a good thing we had that report from Florida for had we not made it that one day, the weather was bad for the next two weeks. Also, it is extremely hazardous to fly into unknown weather when you are forced to stretch your fuel supply.

During this flight was the only time we lost ham communications. Nothing could be heard on the receiver. Later I found it was just a short in the speaker plug, but it did put us out of business. The boys in Florida did hear my transmissions, I learned later. On landing at Key West, I phoned Arthur immediately and relieved the concern of the many stations listening.

As with automobile mobile, air mobile is more useful on a long trip than on a short trip. I feel that it is a must for trips outside the country where public communications may be spotty. It has certainly proven itself to be very useful. . . . W3ZP

FM Subcarrier Generator for Ham TV

Amateur television, or ATV, is beginning to become quite popular. The availability of inexpensive vidicon cameras and the many articles appearing in ham magazines about TV have made it possible for the ham who wants something different, but not too difficult or expensive, to try ATV. However, one big problem of ATV'ers has been transmitting audio. One method is to use a completely separate transmitter and receiver system, as for example on two meters. This requires a lot of extra equipment and cost, and means that your audio cannot be received on a standard TV set used for video reception with a converter.

Another method of transmitting audio is to use a completely separate transmitter 4.5 MHz away from the video carrier and either feed the audio signal to another antenna or through a complex diplexer to the common 440 MHz TV antenna. This method is also expensive as it requires a complete transmitter and power supply for audio.

A better approach, I feel, is the simple

4.5 MHz FM subscriber generator described in this article. It produces more than 1 V P-P carrier which can be fed into your video modulator either at the camera end of the cable, or at the modulator. The components are not critical; the transistors can be almost any of the inexpensive new epoxy-cased types.

The circuit (shown in Fig. 1) consists of two stages of audio amplification from a high-Z microphone feeding a Varicap-controlled oscillator at about 4.5 MHz. The Varicap changes capacitance at an audio rate giving true FM output. The fourth transistor is used for isolation and to provide a low impedance output.

The generator can be built in many different ways: Vector board, Veroboard, etched circuit board, etc. A convenient method is to use plain insulating board with holes drilled for components and jumper wires for connectors. Care should be taken to prevent ground loops or pick up from long leads if used on the same chassis with a transmitter

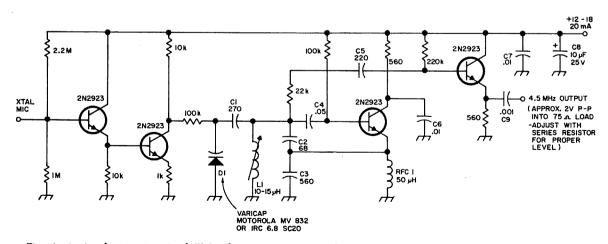

Fig. I. A simple transistorized FM subcarrier generator for transmitting audio on a video transmitter.

! ADD PUNCH AND CLARITY TO YOUR SIGNAL!

NEW

COMDEL SPEECH PROCESSOR MODEL CSP 11

A prototype of the CSP II has proved itself an effective communication aid on the amateur bands over several years. Its prominent feature is the instantaneous limiting action without the harmonic distortion which often makes the use of conventional speech clippers marginal, particularly with SSB transmitters. Designed for relatively insensitive high Z microphones—a gain control is provided—the unit will enhance the intelligibility of voice signals considerably under difficult conditions. "MIL" design and construction is employed throughout for high reliability and long life. Power is obtained from internal batteries (6 "D" cells—life exceeds 300 hours) or external source. Free brochure will be sent on request.

PRICE: \$111.00 POST PAID IN U.S.A. (Mass. residents add 3% tax)

COMDEL INC.—218 BAY ROAD—HAMILTON, MASS.—01982

and modulator. The best way to wire the circuit is in the same order as the schematic.

The generator is easy to test. Apply power, and if nothing smokes, listen for a signal on a general coverage receiver tuned to 4.5 MHz. Adjust the slug of L1 if necessary. Then connect a crystal or high impedance dynamic mike and check for FM audio output by listening to the receiver. If you don't have a receiver that covers 4.5 MHz, you can connect the generator to your video monitor if it has an audio as well as video input, or connect the generator to your modulator and transmit on the air.

Unless you have a scope with response out to 5 MHz, it is hard to tell how much audio subcarrier voltage to out with the video. The usual ratio is 1 V video to ¼ V P-P audio at the modulator input. This is assuming that your modulator is flat out to 5 MHz. If it is not, then you can peak it up at 4.5 MHz by adding a tuned circuit as shown in Fig. 2. This added circuit may give you greater definition, too.

Now as for the transmitter, tune the final to favor the upper sideband since your receiver is tuned that way. The only drawback with this system is that the audio is going out on the video carrier, and subtracts a little power from it. It's only a small amount, and shouldn't make much difference.

This method has been used successfully in the Los Angeles area. It enables simultaneous conversation between hte transmitting and receiving stations for quicker and better fine adjustments.

For any reader who doesn't feel like making his own generator, I can supply the finished unit on a printed circuit board for \$15 postpaid.

A Low-Cost Vertical Antenna

A number of manufacturers make simple vertical antennas with loading coils. These antennas take little space, work on all bands, and perform well. Here's a home-made version of this type of vertical antenna that can be made very easily. The drawing tells how to make it. Adjustment is very easy. For eighty meters, set the shorting tap about one-third of the way down the coil. The feed line should be set a few turns up from ground for a starter. Then try different settings until the SWR is as low as you need to get it. I get about 1.1:1 at 3.68 MHz. So far I have worked stations in Alabama and out to the East Coast during the evening hours, and stations in the surrounding states during the day on 80 meters. My signal reports were no lower than S-7 using about 160 watts input. Total cost was under \$5. . . . John Sharples WA9MYR

James Dandy Diode Tester

Jim Asha W2DXH Freeville, N. Y.

If you've wondered how to check the condition and characteristics of junk box diodes, here's an article for you. It's a simple, inexpensive tester for low voltage diodes.

I think that semiconductor diodes are almost as useful in circuit construction as resistors and capacitors. Used properly, diodes are good for all sorts of tricks beyond detecting rf and rectifying ac. Well, I recently saw a chance to acquire a huge batch of assorted computer types at an irresistible price (five dollars), and my resistance being what it is, I bought them all. But when I got them into my lab, a new perspective emerged: which ones are good? As I was sorting out the color coded varieties, I developed an idea.

Like Topsy, the idea growed up! It became a schematic and some simple calculations. It developed into a mess of clip leads and components attached to a Heathkit oscilloscope. And finally I built . . . a James Dandy Diode Tester.

This simple circuit tells which end of the diode is which, what its reverse breakdown characteristics are, and it gives you a rough indication of quality. You'll have to try something else if you're interested in determining rf performance or pulse risetime and turnoff characteristics, but you can tell if it's worth further attention. The Tester also checks zeners and transistors by observing the properties of their inherent diodes. And maybe

TO SCOPE VERT. INPUT

ISO VAC
INPUT

6.3 VAC

DIODE CASE

Fig. 1. Basic circuit of the Tester.

there are one or two other uses we can find for it.

Theory

If we pare all the trimmings off the James Dandy Tester schematic, we end up with Fig. 1. This shows a high-voltage transformer in series with a resistor and a diode, and an output terminal added across the diode. Note that the diode points up. A second winding which provides the scope sweep voltage is not needed for a basic explanation. So let's work out what happens when the circuit is turned on. The key lies in the diode properties of reverse breakdown, forward conduction, and internal resistance.

The dotted box in Fig. 1 represents the shell of the real diode. Electronically we can never open up this shell and find something inside that visibly accounts for what the diode does. But we can suppose there's a perfect diode inside the shell, and a resistor that somewhat spoils the diode's properties. Then we can describe the real diode's behavior in terms of this model. My diode-

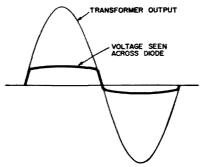

Fig. 2. Where the diode characteristics curve comes from.

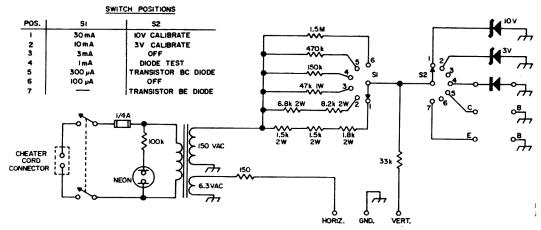

Fig. 3. Complete schematic of the James Dandy Diode Tester.

resistor model is very simple but it'll get by for now. So let's say the perfect diode goes into reverse breakdown at 20 volts, forward conduction at 0.7 volts (appropriate for sliresistor has the rather high value of 100 con, choose 0.2 volts for germanium) and the ohms.

Fig. 2 illustrates the resulting situation with two superimposed curves. The upper curve represents the 150 volt RMS sine wave, always seen at the transformer terminals. The lower curve shows what we see at the diode terminals, generally a much lower voltage. Let's follow this through a complete cycle.

Starting at zero volts and going in the positive direction, we follow the sine wave along its natural course until it reaches 20 volts. At this level the diode goes into conduction, and the circuit sees the 100-ohm resistor as a heavy load with its bottom end held at 20 volts. This state continues until the transformer's sine wave returns to the 20 volt level on its downward swing. Then the diode goes off, we return to the sine curve, and follow its natural course back to zero.

The 150 volt RMS wave goes to 212 volts peak at the center of the half-cycle. We see roughly 200 volts across 10 Kilohms, or about 20 mA at this instant. Passing through the diode's 100 ohms, this current adds 2 volts to the perfect diode's 20 volts. We will have to push the top of the diode voltage curve up a little bit, and we should round off the corners since that's what we expect to find in a real circuit. This is how we get Fig. 2, which very closely resembles the real curves you will observe using a triggered or sawtooth sweep.

The negative half-cycle closely resembles the positive curve, but the break points are very much closer to zero. The (silicon) diode takes over at 0.7 volts rather than 20 volts, and the curve bulges in the opposite direction because the current flow is reversed.

My transformer has a 6-volt heater winding which I put to use as a horizontal sweep source. This gives a linear presentation. That is, starting at the center of the trace, which should rise towards the right, percentage of distance to the end equals percentage of peak applied voltage. This eliminates using a simple trig equation if you want to know the diode current at any part of the curve. And it gives a presentation closely resembling the manual and textbook illustrations. By changing some output connections you can get an exact correspondence.

Depending upon conditions of operation, 200 volts or more can appear at the Tester output terminals. If you're looking at fine detail in the diode characteristics, this could be applied directly to your scope's input tube. The 33k resistor in series with the vertical output terminal limits current flow under these and short-circuits conditions to

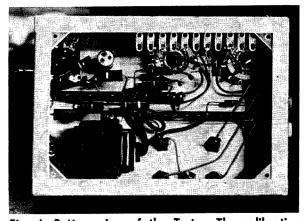

Fig. 4. Bottom view of the Tester. The calibration zeners are on the lug strip at the upper right hand corner of the chassis.

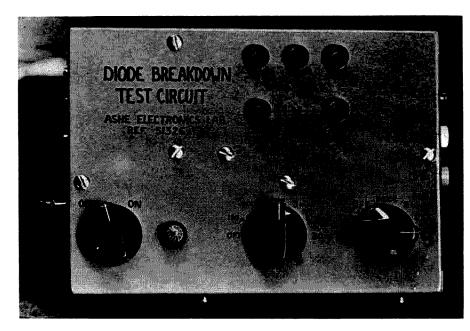

Fig. 5. Top view. I finished the Tester with slow-drying enamel and freehand India ink lettering.

5 mA or so at the price of a slight loss in signal amplitude. A much larger current is available at the diode test terminals, so watch your fingers! Turn the Tester off when changing diodes.

Construction

Fig. 3 shows a complete schematic of the Tester. Those protective resistors and the two-pole power switch might seem a little elaborate to you. But I've been in this field for some time and I think I've blown as big fuses as anybody, and got bit a few times too. The lots of little precautions like these tucked away in everything I build add up to a pretty fair insurance policy for me as well as the gear.

A 5x7x2 chassis serves as case and panel,

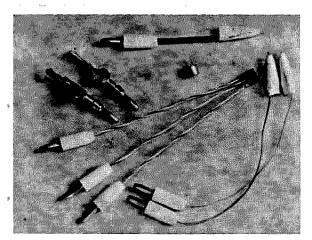

Fig. 6. Assorted leads for the tester. They go well with the Heathkit transistor tester too.

and a bottom plate makes a worthwhile improvement. All wiring is point-to-point, and three 11-lug solder strips provide additional useful tie points. About half the lugs actually got used. Fig. 4 shows a bottom view of the Tester.

You can see the transformer in the lower left hand corner of the chassis. If your transformer won't go in upside down there is lots of room on the back wall. The AC cheater-cord connector goes in the LH side wall beside the transformer, with a half-inch of clearance around its solder lugs. The fuse-holder is in the same wall perhaps two inches forward. There wasn't enough room for it on the top, and fuseholders aren't very interesting anyway. I might have used a TV solder-in fuse and saved cutting a hole.

On the top surface, three rotary switches and a neon pilot lamp are mounted on the same line slightly more than one inch from the front wall. See Fig. 5. With the transistor and diode terminals toward the rear, there is a clear area across the inside of the chassis which takes two of the three 11-lug strips.

I used banana jacks for all test and output connections. They seem to be more convenient than anything else. Fig. 6 shows a collection of connecting adapters made up for the Tester. The ones on the left are made up of Grayhill #2-0 breadboarding terminals soldered onto banana plugs, and they are particularly handy when testing diodes. The others are make up of banana plugs and some light and some heavy wire, with Mueller's micro-gator clips. The more common alligator

clips just don't get a grip on fine wires and transistors leads. Somewhere in there is a transistor socket with short leads, which I might have color-coded emitter yellow, base green, and collector blue. These assorted adapter leads tend to congregate on my Heathkit transistor tester when I'm not checking diodes.

A rotary switch turns the power on and off. I always use a rotary switch in this critical location. A toggle switch could collapse someday, accidentally turning on the circuit. A rotary switch can't possibly do that,

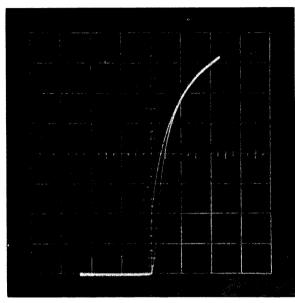

Fig. 7A. Germanium diode characteristics, showing gradual breakdown with increasing reverse voltage, and low forward resistance.

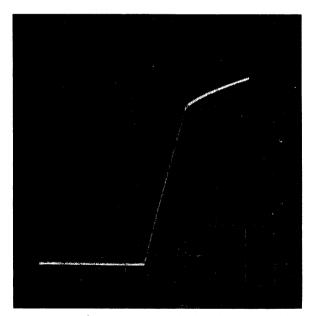

Fig. 7B. Another germanium diode, showing a sharp knee but poor dynamic resistance.

and its general health is immediately apparent just by looking at it. I like that.

The other two switches are single-pole non-shorting (make after break) rotary switches, and any of several varieties are usable. Mine were assembled from CTS parts, purchased in little boxes and then you assemble what you need. I see some nice switches in Allied's #260B catalog on page 308. They are Mallory's Series 3200J non-shorting single-gang switches, and they come already assembled.

When you are finishing up the circuit, leave the transformer heater leads a little loose. You may want to reverse them. Before you finalize things, hook up the tester to a scope, set the scope to very low vertical sensitivity, and see which way the trace goes. It should be a straight line, rising to the right. That is, if a positive voltage to the scope's vertical input deflects the spot upwards, and to the horizontal input deflects the spot to the right. Otherwise you may have to redraw the curves shown in the illustrations.

The calibrating diodes go in last. Finish up everything else, and use the Tester to choose them. They'll be zeners or other diodes that show good zener characteristics. Details follow shortly.

Component values in this circuit are not critical because I don't expect too much from it. If I need exact measurements I get them somewhere else. I've chosen properly sized resistors so you can leave it on all night without anything roasting. If you want to change those resistors, it's easy. Ohm's Law:

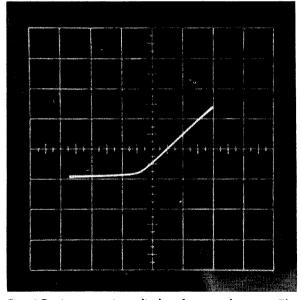

Fig. 7C. A germanium diode after overheating. The scope gain is very high, so we see that its diode characteristics are nearly gone.

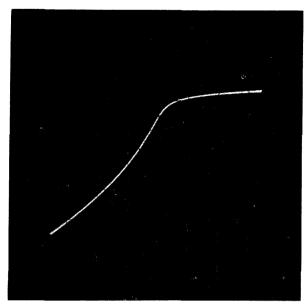

Fig. 8A. BE diode of a germanium transistor. Downward curve indicates a PNP transistor, and rather vague conduction and reverse characteristics suggest high leakage.

RMS voltage over resistance equals RMS current, and you can see in Fig. 5 which values I chose. If you can't find a 150 volt transformer, compute new resistances for what you have available. I wouldn't use a lower voltage because some transistors and small diodes show breakdown voltages in the 100-volt range.

The case is finished off with good enamel and careful hand lettering. I won't go into detail on that because it's pretty well covered by my article on the subject in the March 1967 73.

The calibrating zeners

If you have a scope with fixed voltage ranges, you probably aren't interested in the calibrating zeners. If not, you need them, but how are you going to find out what their values are?

Perhaps you have some zeners of known characteristics, but the usual 10%, 20% or greater tolerances seem rather excessive. If you're familiar with your VTVM, you may have guessed the answer already: use its ability to indicate peak-to-peak AC voltages.

A review of the meter manual should answer any questions that may arise. So far as I know, all inexpensive VTVM's use a peak-reading circuit, with a meter scale that is labeled for sine-wave readings. We'll just convert those estimated sine-wave figures right back to P-P, by multiplying by 2.82. Or perhaps, like my Paco, P-P scales are

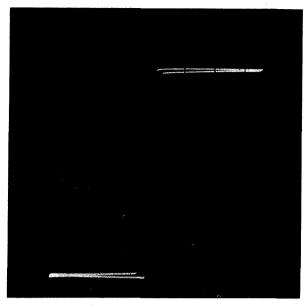

Fig. 8B. BC characteristics of the same transistor. This curve is also downward, and it shows a very sharp conduction and breakdown knee.

included on the meter face.

Set up the Tester and your oscilloscope. Attach your meter ground lead to the Tester ground return, and the meter probe to the scope Vertical Input terminal. Set the VTVM for AC measurements and start testing diodes. When you come to a diode that has nice sharp corners and flat top and bottom, make an RMS reading, convert to P-P, and you have that diode calibrated. I think 3 volts is a little low, because I went through nearly a hundred diodes and transistors before I found one of this value; you might try 5 volts and you'll find one quickly. Three more of them would add up to 15 volts, and these are probably better choices than 3 and 10 volts.

Remember to make your measurements at the same current you will use when calibrating the scope. My zeners give true readings at 1 mA; you'll get sharp corners more easily at a higher current.

Testing diodes

The quickest way to understand the Tester indications is to put a diode in it and then work out the meaning of the different parts of the curve. Repeat with several different diodes. Most everything you need to know is in the theory section, and in several widely distributed handbooks. Just take a little bit at a time and ask, how did it get that way? I've included some illustrative photos and

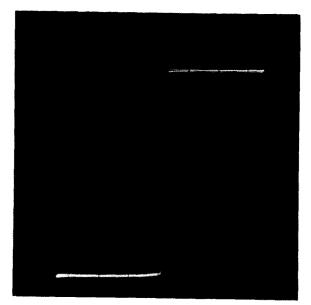

Fig. 9A. It's not obvious here, but this silicon transistor BE diode curve turns upwards.

brief explanations.

All bipolar transistors have two inherent diodes. One is the base-emitter diode, and the other is the base-collector diode. The Tester checks these diodes one at a time, and it doesn't tell you anything about how the transistor will work. But if one of the diodes is bad, the transistor won't work. And the direction the curve goes indicates whether you have a PNP or an NPN transistor. See Figs. 8 and 9.

Why do many diodes show a double line in the vertical parts of the pattern? These lines merge at higher currents but are very distinctly separate for small currents and large diodes. I think this is phase shift of the applied voltage through the RC network of series resistor and reverse-biased diode capacitance before it goes into breakdown. In that case, the LH line would be the right-ward-going trace (phase retarded).

Zener regulators

Do you have trouble finding zener regulators? The Tester will find lots of them, and tell you how they'll work in your circuits. It's so handy for checking zeners it belongs in my zeners article (73, October 1966) but when I wrote that I hadn't thought of it yet.

It turns out that not only specially built silicon diodes will serves as zener regulators, but some unspecial diodes and even germanium transistors! The Tester finds the ones that can regulate, and some of you out there

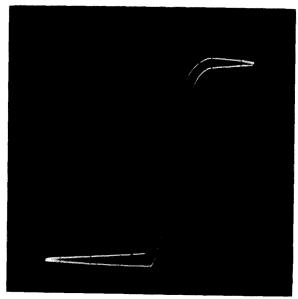

Fig. 9B. BC characteristics of the same transistor. I don't know what causes the very noticeable phase shift. Can somebody tell me?

working with low-power circuits can now find very low-power zeners to go with them. Wish I'd found out about this sooner! I haven't done any work in the matter, but I expect germanium zeners aren't going to show as good temperature stability as silicon zeners. Well, that is another problem. Fig. 11 shows the base-emitter breakdown characteristics of an unlabeled germanium computer transistor from somebody's printed circuit board.

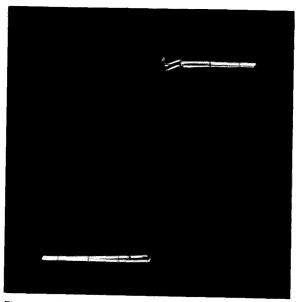

Fig. 10. A very close look at a perfectly good GE Z4XL6.2 zener diode. It shows some zener noise under 200 microamps, and low dynamic resistance.

Closing comments

The Tester can supply lots more power than is required to roast a good diode into complete uselessness. Fortunately, this is harder to do than you might think. The power dissipated in the device is the usual product of voltage times current, and since most transistors and diodes break down at under 20 volts, and can take over 100 milliwatts ,the average danger line lies around 5 mA. But some transistor may unexpectedly show a base-collector breakdown at 50 volts or more, and if it's rated at 60 mW you may easily overdo things. I hope you'll try to roast a few semiconductors to get a feel for what you can and cannot get away with . . . just watch the scope and you'll see the curve begin to slump off towards a straight line. Then heave the poor thing into a nearby wastebasket so it can't end up in one of your circuits.

If you're careful to use things only for their intended purposes, you are missing a lot of fun. What can you do with the Tester? Try a little neon lamp at low current. Another thought that comes right to mind is that perhaps it can be used in some way to check computer switching cores. I'm sure you can work up some new ideas. And as you puzzle them out you'll pick up a few pointers enabling you to make better use of this simple but surprisingly handy James Dandy Tester.

Some Commandments for DXing

Considering that the avalanche of DX activity has continued unabated through the worst of the past sunspot cycle, it seems logical to presume that the future months of increased sunspot activity will bring more and more "country-chasers" to the 80-10 meter bands. Therefore, in order to prescribe some measure of order in the impending chaos, it was decided to formulate a Ten Commandments of DXing. What finally emerged does not quite qualify for this dignified title, although there are ten rather broad rules, so it is offered to you simply as some commandments for DXing.

- 1. Keep Up To Date: When Gus, Don, Jose, or whoever is making the current DXpedition circuit, are on the road you've got to know about it, because if you miss the places they go it may be a long, long time before you get another chance. There are several good DX publications which furnish the latest possible information on who is going where, when, and what frequencies and modes to listen. Among the leading ones are Gus Browing's DXers Magazine (W4BPD), the West Gulf DX Bulletin (W5IGJ), Geoff Watts DX News-Sheet from England, and DX-Press (PAØLOU) from the Netherlands.
- 2. Never Make More Than One QSO per Band per Mode—with a DXpedition, or better yet on the very rare ones keep it to one QSO PERIOD. DXpeditions are usually staffed by good operators. If you work him you'll be in the log so there is no need to deprive others of a chance by making repeat contacts.
- 3. Listen to Instructions: If Don says, "Tuning up 5," then for crying out loud stay off his frequency, and if he says call again, "Only the station ending in item, foxtrot," then chances are it's my turn so

- give me a chance. If he says, "QRZ W7's only", then give the 7's a chance. Your turn will come.
- 4. Watch Conditions: If the rare one is S4 at your QTH, but is passing out 40 over 9 reports to some other call area then chances are you can shout your head off for an hour with a Texas kilowatt and get no results. However, when he is 40 over 9 at your place you can frequently work him with 50 watts.
- 5. Keep Your Call's Short: If you call W9WNV/HKØ three times and then sign your own call three times, Don will probably make four more contacts before you finish generating QRM on the frequency.
- 6. Hear Him Before You Call Him: You may hear W4DQH working YK1AA, but that doesn't mean you can copy Rasheed at your QTH. However, you can sure make ORM for the ones who do hear him.
- 7. Don't Try to Ragchew With the Rare One: Many rare DX stations enjoy a good ragchew and it's certainly their privilege. Nobody wants to give nothing but RST's to W,K's all day long, but if he is working them contest style let him. It's up to him to decide when to stop and shoot the bull for a while.
- 8. Don't Tie Up the DX Station with Requests for an address; he could be making three or four more contacts. There are plenty of ways to lnd out an address, try the Callbook, the QSL Manager's Directory, your DX Association bulletin, or the listings in QST and CQ.
- 9. Avoid Long CQ Calls: These are a symptom of lid-itis. Short CQs by new DXers with only a short list of countries confirmed are justifiable, but good DXers spend most of their time listening. For Petes sake don't be the fink who calls CQ DX in the

middle of a pileup. This is the crowning mark of the number one lunkhead. and last but very, very far from least:

10. Always Keep Your Logs in Greenwich Mean Time (GMT): When a QSL manager sits down to make out three or four thousand cards he doesn't have time to convert Lower Slobbovian Daylight Saving Time to GMT. If he did it would take him four times as long and your precious card would probably end up in File 13.

This is really not the end. This list could keep going, doubtless you have thought of a few that I have missed. Worthy of note also are: Don't Tailend, Don't break the SSB station on 14.110 with CW when he says no CW please (Argh!!!), Don't ask the rare one to stand by for your buddy when there is a big pileup calling him, etc.

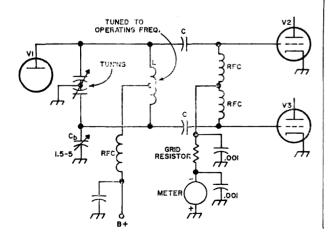

Happy DXing everybody. Really its a lot of fun.

. . . K4IIF

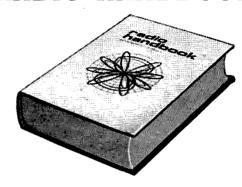

Capacitively-Coupled Phase Inverter

The most common phase inverter for rf is an inductively coupled transformer with the grid coil center tapped. However, at times it is difficult to use inductive coupling. The circuit shown is a method of phase inversion using capacitive coupling. Trimmer Cb is adjusted to approximately the output capacitance of V1 to balance the plate coil. Coupling capacitors C should be the same value. About 100 pF works fine on VHF and 500 pF on HF. On VHF the tuning capacitor should be a miniature butterfly. On the lower frequencies, a ganged tuning capacitor will work. I have had excellent results using this circuit.

17TH EDITION of the world-famous RADIO HANDROOK

- Most comprehensive how-to-build-it source
- Problem-solver for designers & builders

Completely revised and enlarged by William I. Orr, W6SAI. This is the comprehensive communications manual which is the industry standard for electronics engineers, technicans, and advanced radio amateurs. Explains in authoritative detail how to design and build all types of radio communications equipment.

LATEST HOW-TO-BUILD DATA

The new 17th Edition of the RADIO HANDBOOK presents design data on the latest amplifiers, transmitters, receivers, and transceivers. Includes greatly enlarged sections on single-sideband equipment and design, and semiconductors. Gives extended coverage to r-f amplifiers, special vacuum-tube circuits, and computers. All equipment described is of modern design, free of TVI-producing problems.

THOROUGHLY REVISED & UPDATED

Provides a complete understanding of the theory and construction of all modern circuitry, semiconductors, antennas, power supplies; full data on workshop practice, test equipment, radio math and calculations. Includes aspects of the industrial and military electronics fields of special interest to the engineer and advanced amateur. The 17th Edition of the RADIO HANDBOOK provides the broadest coverage in the field—complete information on building and operating a comprehensive variety of highperformance equipment. All data is clearly indexed. 832 pages; $6\frac{1}{2}$ x $9\frac{1}{4}$ "; hardbound. Invaluable for amateurs. electronics engineers. and designers.

A Solid-State RTTY Indicator

So you've built that solid-state RTTY converter, and can't use it because you can't tune signals with it? The best way to tune is with a scope, but that \$60 and anyway, a scope is inconvenient to carry on demonstrations.

Well, here's a small, solid-state indicator for both mark and space. It uses two #47 light bulbs, four resistors, four 2N697 transistors and two 1N270 diodes. The unit is smaller and lighter than a silver dollar. I etched a copper-clad board and mounted the works on it, but a peg board would work just as well. Take your choice. Connect up as in Fig. 1, which shows only one of the two channels. They are identical except that R_L may be different. This resistor will have to be closed empherically. To adjust connect the completed unit to both the mark and space filters and to the power supply. Connect a 100 k Ω pot in place of each R_L and adjust for proper results on a received signal. The unit will trigger at approximately 0.02 mA and 3 V. I believe you will be very pleased with the operation of this unit, as I have.

. . . E. C. Sherrill K6JFP

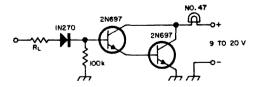

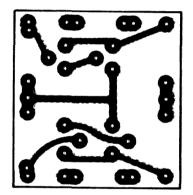

Fig. 1. Schematic diagram of one channel of the RTTY indicator.

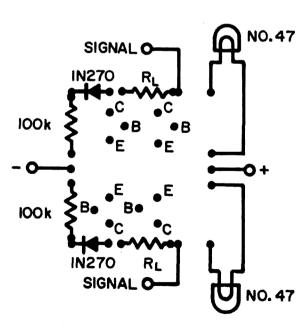

Fig. 2. Full-size drawing of the layout for the etched circuit board.

SUB-MINIATURE SOLID STATE

TV CAMERA

FOR CLOSED CIRCUIT OR AMATEUR TV

THE VANGUARD 501 is a completely automatic closed circuit television camera capable of transmitting sharp, clear, live pictures to one or more TV sets of your choice via a low-cost antenna cable (RG-59U) up to a distance of 1000 ft without the need for accessories or modifications on the TV sets. The range can be extended indefinitely by using line amplifiers at repeated intervals or by using radio transmitters where regulations permit.

There are hundreds of practical uses in business, home, school, etc. for any purpose that requires you or anyone chosen to observe anything taking place anywhere the camera is placed. Designed for continuous unattended operation, the all-transistor circuitry of the 501 consumes only 7 watts of power.

SPECIFICATIONS:

- Measures 234" x 4" x 7" (excluding lens and connecters).
- Weighs 31/2 lbs.
- Operates on 100-130 volts 50 or 60 cycles, 7 watts.
- Tested at 10° to 125° F.
- Advanced circuitry utilizing 35 semi-conductors most of which are silicon.
- Field effect input circuit for minimum video noise.
- Resolution guaranteed to exceed standards set by 525 line TV receivers.
- RF output 30,000 microvolts adjustable for channels 2 to 6.
- Video output 1.5V p-p composite with standard negative sync (random interlace).
- Viewable pictures obtainable with illumination as low as 1 ft, candle.
- Vidicon controlled light compensation; 150/1.
- Adjustable iris on lens enables use in bright sunlight.
- New long life, sub-miniature vidicon with spectral response similar to Type 7735A.
- Electronically regulated power supply and thermally compensated circuits eliminate change in picture quality when line voltage and temperature fluctuate.
- All parts guaranteed for 1 year (except for open filament on vidicon or breakage).
- Fast, low-cost service always available from our factory in Holiis, N.Y.

Pre-set adjustable controls include the following: Videe gain, video compensation, pedestal level, target voltage, beam voltage, beam alignment. electrical fosus, horizontal frequency, horizontal size, vertical frequency, vertical size, vertical linearity, modulation and RF frequency output.

Send your order direct to our factory

Bullt-In Speaker

In the old days when it was fashionable for ham gear to be large and heavy, a separate speaker was the mark of a quality receiver. A separate speaker was also necessary to prevent howls from mechanical feedback.

Today we have rock stable equipment, and small speakers of good quality, and it is often possible to mount the speaker inside the equipment.

Here is a 3½ inch speaker installed in an HW-12. The little brackets are glued on with epoxy cement to avoid drilling holes. The wires were fed through the gap between the chassis and the front panel. No parts had to be moved, and all components are still accessible. The sound comes out through the ventilating holes, and the speaker cannot be seen. Although many speakers can be used, one with a one-ounce magnet will be louder. It makes little difference if it is 3.2 ohm or 8 ohm.

Having the speaker in the set means one less cable to disconnect when moving the rig from house to car.

. . . Edward Romney WA1FTV

WWV on the Drake R-4A

Users of Drake R-4A receivers may receive WWV on 5 MHz without buying additional crystals or modifying the unit. Set the band switch to 3.5, the preselector to about 5.3 and switch on the calibrator. Tune in the calibration signal with the VFO dial reading between 630-635 and peak with the preselector. Switch off the calibrator and under proper conditions WWV can be received.

. . . Bob Fransen VE6TW

Reduction of Transformer Voltage

Here's a neat trick to reduce the high voltage output of a power transformer a small amount when used as a transmitting plate transformer. It's especially useful when an old TV transformer from the junk box is pressed into service with a silicon diode voltage doubler or full wave bridge, and the resulting dc output voltage is found to be just a little too high for comfort, as is frequently the case.

Simply wire one or more of the unused filament windings in series aiding with the 117 volt primary winding to obtain the effect of a few more turns in the primary. Various combinations are possible because the 5.0 volt rectifier filament winding can be used to subtract from a 6.3 volt winding if only a small reduction is desired. The current rating of the filament windings is no problem because they are usually wound from much heavier gauge wire than the primary itself.

Caution: Don't try the reverse of this trick; that is, increasing the output voltage of an inadequate transformer by wiring the filament windings in series opposing. The extra voltage which would result would saturate the core iron, resulting in increased hysteresis losses in the core and excessive heating of the transformer. The only exception would be to correct for a known low input voltage, but care must be exercised not to exceed the rated voltage of the transformer secondary in any case.

This trick has been used very successfully here at K8SCM and frequently spells the difference between using an old "junker" transformer in a critical power supply or shelling out a lot of bucks to buy that special-order job which will furnish the exact voltage the schematics call for.

. . . John Copeland K8SCM

NEW! IMPROVED! SOLID STATE FREQUENCY CONVERTERS

Priced from only \$14.95 +0 \$39.95

OVER 5000 FREQUENCY COMBINATIONS FROM .45 MC TO 475 MC AVAILABLE FROM STOCK.

MANY NEW MODELS TO CHOOSE FROM OFFERING A TOTAL OF THE FOLLOWING: Crystal control, variable tuning, UHF epitaxial transistors. FET transistors, noise figures as low as 2.0 db, full wave varactor diode transistor protection, sensitivity better than 2/10 microvolt, fully shielded oscillators and band-pass filters to eliminate spurious frequencies, zener diode voltage regulation, 6 to 12 volts positive or negative ground, slug tuned coils, double tuned R.F. stages, tuned mixer stages, wide band I.F. amplifiers. All this plus the highest quality components carefully assembled, tested, and guaranteed.

We have exactly what you want at a lower price and better quality than you can obtain elsewhere. See our new multiple oscillator converters for monitoring two or more frequencies simultaneously!

24-hour special delivery service available on many models.

High Frequency Single Sideband Receivers, Transmitters And Transceivers

Jim Fisk WIDTY Technical Editor

Babcock B-500-SSB Transceiver

The new Babcock B-550-SSB is claimed to be the world's most advanced transceiver, utilizing techniques that significantly extend the state of the transceiver art. This completely self-contained unit uses the advantages of modular construction and provides high efficiency performance on SSB, CW and AM.

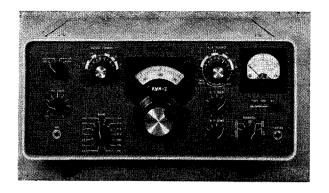

With the exception of the 12BY7A driver and 4CX250B final amplifier, all the circuits in the B-500-SSB use transistors or integrated circuits. A total of thirteen integrated circuits are used in conjunction with silicon transistors and diodes. The front end of the receiver uses two field effect transistors in cascode along with another FET in the first mixer. This combination results in

a noise figure of 4 dB, sensitivity of at least $0.5~\mu V$ on all bands and crosstalk rejection on the order of 96 dB.

The B-500-SSB covers all the ham bands from 80 through 10 meters in eight 500 kHz segments. Two precision VFO's are built in, and each provides calibration at the 100 Hz points. The receive VFO permits independent receiver for working out of band DX stations.

The power input on all bands is 600 watts PEP on sideband, 250 watts on CW and 500 watts PEP on AM with the optional B-500-AM plate modulator. For maximum efficiency and linearity, the final 4CX250B is run in class AB₁ on single sideband and in class C for AM and CW. The optional AM modulator is a plug-in unit which mounts conveniently inside the transceiver cabinet.

Other interesting features of the new Babcock B-500-SSB are the built-in supplies for both 115 Vac and 12.6 Vdc, a front end noise blanker which uses its own broadband if amplifier and noise gate, notch filter with notch tuning and depth controls, a level control to eliminate external attenuators when using a linear amplifier, built-in SWR meter, and front panel selection of ALC. For more information on this brand new transceiver, write to L. E. Babcock and Company, 28 Durant Avenue, Maynard, Massachusetts 01754.

Collins KWM-2

The Collins KWM-2 maintains a reputation for outstanding performance in mobile and fixed station applications; in fact, many of these units are being used by the Special Forces in Viet Nam. The KWM-2 will run 175 watts PEP input on SSB or 160 watts on CW, with a nominal output of 100 watts on all bands from 80 through 10. Crystals are provided for complete coverage of all the high frequency ham bands except ten meters, where only one crystal is supplied. There is provision for mounting two more crystals to extend the coverage on the 28 MHz band.

The Collins KWM-2 was the first available amateur mobile SSB transceiver and features a filter type SSB generator with a mechanical filter, automatic load control for boosting average talk power, a *linear* permeability tuned VFO and one kHz calibration on all bands. Compactness and efficiency are achieved by having all tuned circuits and several tubes serve dual roles in transmitting and receiving. For MARS and military applications, the KWM-2A is available. This unit has an additional crystal board which enables the operator to add 14 crystals to cover frequencies outside the amateur bands.

There is a complete line of accessories available for the KWM-2, including the 312B-4 speaker console which has a built in phone patch and directional wattmeter, the 516F-2 AC power supply, the PM-2 lightweight portable power supply, the MP-1 mobile power supply, the 351D-2 mobile mount, the very effective 136B-2 noise blanker and the 399B novice adapter. This latter accessory permits crystal control of the transmit frequency for novice operation.

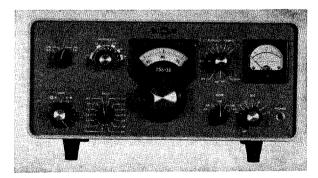

Collins 75S-3B Receiver

The Collins 75S-3B is a very versatile receiver with exceptionally sharp selectivity and operation on either SSB, CW, or RTTY. AM is also provided and the passband can be optimized by the installation of an optional 3.1, 4.0 or 6.0 kHz mechanical filter. In addition, two CW positions offer up to three degrees of selectivity in the CW/SSB mode with optional plug-in filters.

The 75S-3B can be combined with the 32S-3B transmitter to make a completely integrated station. When used with the 32S-3B, this receiver is capable of transceiver-type operation with the receiver VFO controlling the transmitting frequency. Coverage outside the amateur bands or additional 10 meter band coverage is obtained by plugging in the appropriate crystals.

Also available is the 75S-3C which provides extended frequency coverage. It is identical to the 3B except that an additional high frequency crystal board and front panel selector switch are included.

Collins 32S-3B Transmitter

The highly flexible 32S-3B transmitter covers all the amateur bands between 3.5 and 30 MHz with a power input of 175 watts PEP on SSB or 160 watts on CW. The nominal output on all bands is 100 watts. In the 32S-3B, the design engineers have

produced a transmitter with a minimum number of controls for precise tuning and maximum operational efficiency.

The 32S-3B is equipped with crystals for covering eleven 200 kHz bands to cover the ham bands from 3.5 to 30 MHz. Two additional positions are provided for extended coverage of the ten meter band and a third position may be used to cover an additional 200 kHz band in the 9.5 to 15 MHz range.

For CW use, grid block keying is used with adjustment of the characteristic from "soft" to "hard" to suit the individual operator. The 32S-3B may also be adapted to RTTY operation because of the high stability of the unit.

The Collins 32S-3B uses dual conversion with a linear permeability tuned VFO which offers the utmost in stability. The VFO may be used to control the transmit frequency, or when used with the companion 75S-3B receiver, to control the receive frequency. For improved linearity and reduction in distortion products, rf inverse feedback is used along with an automatic load control for higher average talk power.

Drake TR-4

The Drake TR-4 transceiver is engineered for optimum performance on upper or lower sideband, AM and CW. It is compact and lightweight, and is ideal for limited space, for mobile, for vacations or for portable excursions and DXpeditions. With 300 watts PEP input, it will give a good account of itself barefoot or will drive higher power ham linears. The RV-4 receiving VFO solves the problem of working DX and other stations operating on frequencies other than your transmitting frequency.

The TR-4 covers all the amateur frequencies between 3.5 and 30 MHz without the requirement of accessory crystals. In addition, either upper or lower sideband

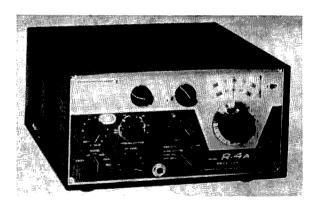

may be used on all bands with full VOX or PTT on both SSB and AM. For CW operation there is provision for automatic transmit and receive switching for semi break-in operation. A built-in CW sidetone oscillator provides monitoring of your CW signal.

The receiver exhibits a sensitivity of less than $0.5 \mu V$ for 10 dB signal to noise and provides full AVC on all modes; the audio output varies less than 3 dB for 60 dB change in signal level.

The sideband generator of the TR-4 uses two special 9 MHz crystal filters to provide upper and lower sideband selection on any band without the necessity of shifting oscillators. The filters are designed so that they are steeper on the carrier side, making sideband suppression of 40 dB and carrier suppression of 50 dB possible. For AM operation a controlled carrier AM screen modulator is built-in; the controlled carrier mode is compatible with SSB linear amplifiers.

On CW the power input is 260 watts and the carrier is shifted approximately 1000 Hz into one sideband. In the CW mode grid block keying is used to key the mixer and driver stages.

For operation from the 115 volt AC line the AC-4 power supply supplies all the necessary voltages. For mobile operation, the MMK-3 mobile mounting kit and 12 volt DC-3 DC power supply are available. For the deluxe installation, an MS-4 matching speaker may be used; this unit has space for mounting the AC-4 power supply in the rear.

Drake R-4A Receiver

The Drake R-4A receiver is a complete ham band receiver that covers all the frequencies on 80 through 15 meters and one 500 kHz segment of our ten meter band between 28.5 and 29.0 MHz. For additional coverage on ten meters or on other 500 kHz segments between 1.5 and 30 MHz, accessory crystals are available.

The R-4A features a tunable passband filter that provides selectable bandwidths of 0.4, 1.2, 2.4, and 4.8 kHz at 6 dB down. At 60 dB down the bandwidths are 2.6, 4.8, 8.2 and 25 kHz respectively. The sensitivity of this receiver is less than 0.5 μ V for 10 dB signal plus noise to noise and the AVC provides less than 3 dB change in audio with a 60 dB change in rf at the front end. In addition, the R-4A has excellent overload and cross modulation characteristics and is quite insensitive to the operation of nearby transmitters.

The Drake R-4A works on all modes, SSB, AM, CW and RTTY, with full rf gain, complete AVC action and accurate S-meter indication. Both the notch filter and 100 kHz calibrator are built in, and an excellent noise blanker provides excellent results on SSB. AM and CW.

The image rejection of the R-4A is greater than 60 dB and the internal spurious responses are less than the equivalent 1 μ V signal on the antenna. Also, if rejection is more than 60 dB. The combination of low spurious and image response along with excellent sensitivity and selectivity add up to an excellent receiver for amateur use.

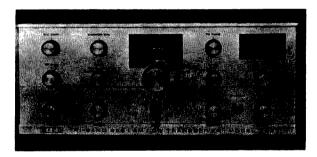

Drake T-4X Transmitter

The Drake T-4X is a complete sideband transmitter which may be used with the Drake R-4A for complete transceiver operation. The T-4X covers the ham bands from 80 to 10 meters with one crystal provided for ten meter operation from 28.5 to 29.0 MHz. Four additional accessory sockets are provided for complete coverage on ten meters or for four 500 kHz bands between 1.8 and 30 MHz. The VFO is a linear per-

meability tuned solid-state unit which is calibrated at the 1 kHz points on all bands.

The use of double tuned circuits and two special crystal lattice filters result in carrier suppression of 60 dB and unwanted sideband suppression of at least 40 dB above 750 Hz. In addition, the average distortion products are in excess of 30 dB down. The input power of the T-4X is 200 watts PEP on SSB and AM and 200 watts on CW. In the CW mode grid block keving is used and the built-in VOX circuit is keved for automatic transmit-receive switching for breakin operation. For RTTY operation, the VFO is easily adaptable to FSK. The signal frequency shifts the same direction and the same amount on all bands with a given dial setting.

The T-4 Reciter (receiver-controlled exciter) is similar in all aspects to the T-4X transmitter except that it does not have a built in VFO. When used with the R-4A, the T-4 provides completes transceive operation.

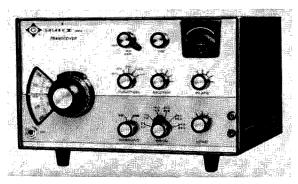

EICO 753

Although the modern sideband transceiver is a very complicated piece of equipment, it is not at all difficult to assemble the EICO 753 sideband transceiver kit. This transceiver has both PTT and VOX and the offset tuning allows you to move the receiver up to 10 kHz away from the transmit frequency. The engineering of this transceiver leaves little to be desired, and the step-by-step instructions are clear and easy to follow. At a time when so much amateur equipment is being bought factory wired, the ham who constructs his own from a kit can feel well satisfied.

The full-band coverage of the 753 actually goes beyond the band edges: 3490 to 4010 kHz, 6990 to 7310 kHz and 13890 to 14410 kHz with lower sideband on 40 and 80 and upper sideband on 20. The VFO is completely solid state and is very stable for either

fixed or mobile operation. Complete VOX is built in with the VOX threshold, delay, sensitivity and anti-VOX controls available on the rear deck.

The power output, 120 watts PEP, is sufficient to drive any linear amplifier, and when used barefoot will give an excellent account of itself. The high level dynamic ALC circuitry controls splattering and flattopping as well as linear amplifier loading. For the ham who doesn't want to roll his own, EICO has conveniently made a factory assembled version available for \$299.95.

Galaxy V Mark 2

The new Galaxy V Mark 2 transceiver maintains all of the features of the old model, but adds some new things to make a very nice package better. This new transceiver is rated at 400 watts PEP in SSB service, up 100 watts from the old model, has a new precise vernier logging scale that lets you interpolate accurately down to 50 Hz or so, a solid state VFO for improved frequency stability and drift and a built-in audio sidetone for the CW boys. In addition, there is a new CW filter and break-in option available if you want the maximum in CW operating convenience.

The excellent sensitivity of the Galaxy V, less that $0.5~\mu V$ for 10~dB signal to noise ratio, and the extremely good shape factor of the *if* passband provide very good results on our crowded bands. The dual attack and release AVC make the receiver virtually block proof. For increased power and minimum flat-topping and distortion, the internal ALC circuit provides up to 10~dB of compression.

This unit is lightweight and compact, and is an ideal choice for mobile operation. For mobile use, the G35A DC supply furnishes all the necessary voltages; for fixed station use, the AC35 AC power supply is available.

Other accessories which are available are a remote VFO for working stations off your transmit frequency, a deluxe accessory console which has a built-in speaker, phone patch, SWR bridge and 24 hour digital clock, a speaker console which has provision for mounting the AC power supply, and several accessories for mounting the Galaxy V Mark 2 in your car.

Hallicrafters SR-500 Tornado

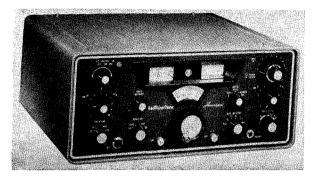

The Hallicrafters SR-500 Tornado transceiver provides the amateur with high-performance SSB and CW operation on the three most popular ham bands; 80, 40 and 20 meters. Lower sideband is used on 80 and 40 meters and upper sideband on 20. The 500 watts PEP input of this transceiver provides an excellent account of itself when run "barefoot."

The transceiver incorporates Hallicrafters' exclusive Amplified Automatic Level Control (AALC) to prevent splatter and final amplifier flat-topping. In addition, the receiver section contains Receiver Incremental Tuning Control (RIT) which allows the operator to tune the receiver up to 3 kHz to either side of the transmitter frequency. All jacks and switching for linear amplifier operation are included as well as a combination S-meter/RF output indicator.

The dial is calibrated in 5 kHz increments, and these are accurate to within 2 kHz between the 100 kHz points when used with an optional crystal calibrator. The stability of the VFO is excellent, and is stable to within 300 Hz after warmup.

Accessories available for the SR-500 include the HA-16 VOX adapter, the P-500 AC power supply for fixed station operation

and a P-500 DC power supply for mobile operation from a 12.6 volt DC power source. For mobile installations the special MR-160 mobile kit is available which includes all the inter-connecting cables.

Hallicrafters SR-2000 Hurricane

The Hallicrafters SR-2000 Hurricane may well be the world's most powerful transceiver-it runs a full 2000 watts PEP input on single sideband. This transceiver has many interesting features in addition to its full legal power rating. A linear gear driven VFO is provided which has less than 1 kHz readout; receiver incremental tuning for working stations off the transmit frequency, built-in amplified automatic level control (AALC), built-in VOX plus CW break-in and PTT. The use of double tuned circuits and steep sided crystal filters results in improved spurious signal rejection and carrier suppression of 50 dB, unwanted sideband suppression of 50 dB and 30 dB suppression of the 3rd and 5th distortion products.

Hallicrafters HT-46

The Hallicrafters HT-46 SSB/CW transmitter provides a potent input power of 175 watts PEP on SSB and 150 watts on CW. It is outstanding as a separate transmitter with a self contained AC power supply, but

its extra versatility is shown by the transceiving capability provided for use with the matching SX-146 receiver. In addition, it may be operated separately from its own internal VFO. Physically it is the same size and appearance as the SX-146 receiver, so it makes an ideal companion to it.

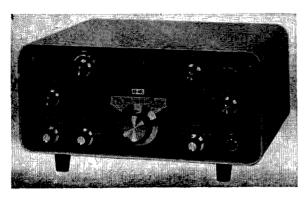

The HT-46 transmitter features advanced crystal filter sideband generation at 9 MHz and selectable sideband operation on all bands. Although only 500 kHz of the ten meter band is provided, accessory crystals are available to cover the complete ten meter band. For use on CW, the grid block keying circuit provides exceptional keying qualities.

Hallicrafters SX-146

The Hallicrafters SX-146 receiver features an advanced design which employs single conversion to a high frequency crystal filter for selectivity. A premixed oscillator chain assures a high order of frequency stability and minimizes adjacent channel cross modulation products. This receiver is supplied with crystals for all the ham bands from 80 to 15 with a 500 kHz segment on ten meters, but the connection of auxiliary oscillators will permit its use from 2 to 30 MHz, except for a small region around 9 MHz, the frequency of the crystal filter. Crystals are available from the manufacturer for complete coverage of the ten meter band.

The selectivity of this receiver as supplied by the factory is 2.1 kHz at the 6 dB points, but optional filters 0.5 kHz and 5.0 kHz wide are available for CW, RTTY and AM operation. The SX-146 provides selectable sideband, a very effective noise limiter and good sensitivity. For transceiver operation, the SX-146 may be used in conjunction with the Hallicrafters HT-46 5 band transmitter.

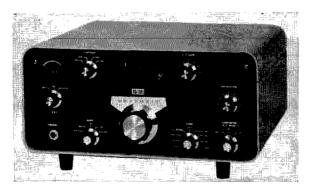

Heathkit SB-401 SSB Transmitter

The Heathkit SB-401 SSB transmitter may be used with the SB-301 receiver for full transceive operation or it may be used independently. The SB-series combination goes from transceive operation to independent transmitter-receiver operation with a flip of a single switch on the SB-401 front panel.

The SB-401 transmitter employs compactron tubes for space-saving component layout, and heavy-duty circuit board construction plus precut wiring harness permits fast assembly and assures stable operating characteristics. For maximum protection from TV interference, all the circuits are completely shielded and isolated.

The VFO in the SB-401 is the same type of linear master oscillator used in the SB-301 receiver. In addition, the SB-401 features built-in ALC, antenna changeover relay, upper or lower sideband selection, 1 kHz dial calibration and full coverage of the amateur bands from 3.5 to 30 MHz.

Heathkit SB-301 Receiver

The new Heathkit SB-301 raises the standards for amateur band receivers and brings full RTTY reception capability to the SB-series plus full coverage of the amateur bands from 80 through 10 meters. In addi-

tion, a 15 to 15.5 MHz tuning range enables the most accurate attainable frequency checks with WWV. The outstanding noise limiter used in the SB-301 provides impulse noise rejection for the receiver and signals in high noise locations are easily readable.

Other features of the SB-301 are the prebuilt linear master oscillator (LMO) which provides receiver tuning with bandspread equivalent to 10 feet per MHz. In addition, it is linear over the entire receiver coverage.

When used with the SB-401 SSB transmitter, the SB-301 provides full transceive operation. The high sensitivity of this receiver, less than 0.3 µV for 10 dB signal-plus-noise to noise, plus the selectivity of 2.1 kHz provide excellent performance. For the RTTY and CW operator, optional crystal filters are available which provide selectivity of 3.75 kHz and 400 Hz respectively at 6 dB down.

Heathkit SB-100 Transceiver

The Heathkit SB-100 transceiver is rated at 180 watts PEP SSB and 170 watts CW with full coverage of the fine ham bands below 30 MHz. The sideband generation circuitry of the SB-100 features a six pole crystal lattice filter which produces a superior 2:1 shape factor and symmetrical passband which results in sharper receiver tuning, greater sideband suppression, and identical characteristics on both upper and lower sideband signals. The carrier is down 50 dB from single tone output, the unwanted sideband is suppressed more than 55 dB and the third order distortion products are 30 dB down.

The new Triple Action Level Control (TALC) uses three separate circuits to provide greater speech compression; is service

the TALC circuit results in 10 dB of speech compression with 0.1 mA final grid current. The use of a linear master oscillator (LMO) provides linear and smooth tuning with 1 kHz calibration on all bands. Both VOX and PTT are built into the SB-100 as well as semi break-in operation for CW; a CW sidetone is also provided.

For operation at a fixed station, the 115 volt HP-23 AC power supply is available. For mobile installations, the HP-13 DC power supply and SBA-100-1 Mobile Mounting Kit will make things easy.

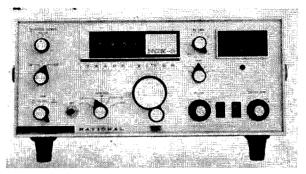

Heathkit 12A, 22A, and 32A Single-Band Transceivers

These new versions of the SSB transceiver that opened up a whole new era in amateur radio have several interesting features. Heath has gone all out to give the radio amateur greater economy and better performance in their famous single-banders. Foremost among the new features of this series is the selectable upper or lower sideband.

In addition the microphone input and gain control, plus bias adjustments are now located on the front panel for ease in changing from fixed station to mobile operation. An added function switch position controls the optional 100 kHz crystal calibrator and the power connectors are now fully compatible with the Heath SB-series power supplies.

The receivers in these new units feature 1 µV sensitivity for 15 dB signal-plus-noise to noise ratio and 2.7 kHz selectivity. The modern crystal filter provides more than 45 dB of carrier and unwanted sideband suppression and the slow AVC action provides optimum SSB reception.

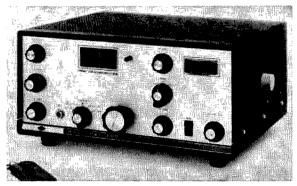

National NCX-5 Mark II

The National NCX-5 Mark II transceiver features 200 watts PEP on sideband, 200 watts CW and 100 watts AM on the popular ham bands from 3.5 to 30 MHz. The 1 kHz dial calibration is accomplished with a technique previously used only in the most expensive laboratory or military equipment—a digital readout in kHz on each amateur band with additional counter calibration to 100 Hz. The tuning rate of 10 kHz per knob revolution is identical on all bands and parallax is zero.

The NCX-5 is a double conversion unit with crystal controlled high frequency oscillators on each band and a *linear* solid state VFO. The use of a transistorized VFO eliminates many of the thermal instabilities of vacuum tubes and provides stability from a cold start which is equivelant to that of the best tube-type oscillators after warm-up.

The excellent selectivity characteristics of the NCX-5 are obtained through the use of an eight pole crystal lattice filter. This filter has a shape characteristic of 1.7:1 and 60 dB down the passband is only 4.76 kHz wide; at the 6 dB points the passband of 2.8 kHz uses a minimum of spectrum consistent with pleasing voice quality. With the crystal filter and balanced modulator used in the NCX-5, the carrier suppression is 50 dB, the unwanted sideband suppression is 50 dB and third order distortion products are 30 dB down.

The NCX-5 incorporates selectable sidebands on all ham bands along with transceiver vernier tuning to permit 5 kHz tuning of the receiver independently from the transmitter. For DX operation, the optional VX-501 digital dial VFO is available. The NCX-5 may be operated either with VOX or PTT on both AM or SSB or with grid-block semibreak-in keying on CW. For AM operation a separate AM detector and AM carrier insertion is provided. The National NCX-5 incorporates two rf stages in the receiver section for increased sensitivity and spurious signal rejection, and the fast attack, slow release AVC system provides smooth, clean SSB/CW reception without distortion, clicks, pops or thumps. For the deluxe installation, oiled walnut cabinets are available for the NCX-5, the VX-501 external VFO and the NCX-A AC power supply.

National 200

The new National 200 transceiver gives the radio amateur complete SSB, AM and CW coverage of 80 through 15 and 600 kHz between 28.5 and 29.1 MHz on ten meters at a very reasonable price. For complete coverage of the 10 meter band two additional crystals may be obtained from the National Radio Company. This new transceiver features 200 watt PEP input on all bands. The fast attack, slow release AVC system works on all modes, SSB, CW and AM. For optimum performance, separate product detector and AM detection circuits are used.

To maintain high stability and the same tuning rate on all bands, a premixed crystal controlled front end arrangement is used. The selectivity obtained from the crystal lattice filter is excellent and results in a shape factor of 2.2:1 for high sideband suppression on transmit and rejection of adjacent channel QRM on receive. The solid state balanced modulator used in the National 200 results in more than 50 db of carrier suppression. Third order distortion products are suppressed more than 30 dB at full output and the unwanted sideband is suppressed 40 dB.

The extremely smooth tuning mechanism uses a 45:1 planetary and split gear drive; the dial is calibrated every 5 kHz. For AM and CW operation, the carrier is automatically inserted when switching to these modes. For maximum talk power on SSB and AM, an internal ALC circuit is pro-

vided; an external ALC input is available for use with higher power linear amplifiers.

Sideband Engineers SB-34

The SB-34 transceiver is a complete four band transceiver for 80, 40, 20 and 15 meters, with built-in power supplies for both 115 volts AC and 12 volts DC. The SB-34 is almost completely transistorized with 23 transistors and 20 diodes; the only vacuum tubes used are in the final power amplifier and driver stages. In addition to the built-in power supplies, all the necessary inter-connecting cables are provided with each unit. Since a front panel mounted speaker is included, only a suitable antenna and a microphone are required to put the SB-34 on the air

This transceiver uses a Collins 2.1 kHz mechanical filter for excellent receiver selectivity and a sharp, clean sideband signal. There are no relays inside the SB-34; all the transmit-receive switching is accomplished with solid state circuitry. The VFO tuning dial employs a dual speed mechanism which allows fast dial movement to the desired portion of the band and smooth slow speed drive for positive vernier tuning of a single sideband signal. The sidebands are completely selectable from the front panel and a offset tuning control allows the receiver to be tuned up to 2 kHz from the transmitting frequency.

On DC operation the transmitter filaments may be switched off with a front panel switch for low current operation of the receiver portion. This type of operation is especially desirable for portable or emergency operating conditions; the transceiver only requires 500 mA at 12 volts DC in this standby-receive mode.

Swan 350 and 400

The Swan 350 transceiver is a complete coverage 5-band unit providing SSB, AM and CW; its companion is the Swan 400. The 350, with an appropriate power supply is a complete package requiring only a microphone and an antenna; the 400 requires an external VFO in addition to a power supply, microphone and antenna. The 350 was designed to be a basic transceiver, providing the means for the owner to add the accessories of his own choice.

Accessories available for the Swan 350 include a 100 kHz calibrator, selectable sideband kit, and transistorized VOX. On the other hand, the Swan 400 includes the

calibrator, selectable sideband, built-in speaker and VOX but does not include the VFO. There is a choice of three different VFO's for the model 400, the model 410 which is essentially the same as the VFO used in the 350, the MARS oscillator which provides operation on any crystal controlled frequency between 3 and 30 MHz and the mobile model 406B VFO. The 406B is actually a combination control box and VFO and when used with the Swan 400 permits remote control of a trunk mounted transceiver in your car. It includes the VFO as well as an rf gain control, microphone jack and bandswitching. Any one of these VFO's may be used with the Swan 350 to provide transmit-receive functions on different frequencies.

The power supplies available for the Swan transceiver are also quite extensive. The standard AC supply, the model 117XC is probably the most popular supply, because it is a very husky unit that may be used mobile with the proper Swan conversion kit. For negative grounded cars (12 volt) the model 14X kit is required; for positive grounded cars, the model 14XP is used. These conversion kits are simply modules which plug into the back of the standard 117XC power supply. For the operator who wants to operate mobile only, Swan also has a DC power supply available, the model 14-117.

High Frequency Single Side Band Linear Amplifiers

BTI LK-2000

The BTI LK-2000 is a single tube, grounded grid linear amplifier built to really take it and loafs along at the full legal input. This amplifier is offered in two styles—the floor model console, or the two-unit table top model with a separate power supply. Either model is convertible into the other with a few available conversion parts.

The amplifier tube is the quick-heating Eimac 3-1000Z which has a full 1000 watts plate dissipation and replacement cost of only seventy-eight dollars. More than adequate cooling is provided by using the recommended air cooled socket and chimney along

with a very quiet blower. A unique after cooling feature has been incorporated in the BTI LK-2000 which keeps the blower running from 60 to 90 seconds after the amplifier is turned off.

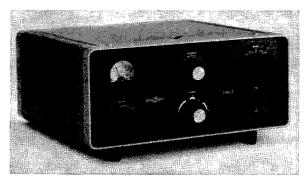

The solid state power supply is built around a husky 40 pound plate transformer; computer grade capacitors provide 30 uF of output capacitance. The combination of a solid state power supply and quick-heat-tube permit almost instant on and off—no warm-up waiting is required. For filament power to the 3-1000Z, a separate filament transformer is mounted in the rf section.

Drive to the 3-1000Z is applied through low-Q broad band tuned input circuits; not over 100 watts of drive is required for full power operation. The LK-2000 performs quite well with only 50 watts of drive and under these condition provides 1500 watts PEP input. Although the cathode input circuits are tuned for amateur band phone operation, they may be retuned by the user for operation at other frequencies with the instructions furnished.

A pi-L output circuit is used to match the plate to the antenna; the pi-L is preferred over the simple pi circuit because of its improved harmonic attenuation. To assure maximum shielding, all cabinet joints of the rf section are alumi-gold processed.

The ALC circuitry used in the BTI LK-2000 provides many distinct advantages; when adjusted according to the instruction manual, the ALC will prevent distortion from overdriving in either the amplifier or the exciter. It allows much freedom in mouth-to-mike distance while maintaining the same full output. Even when you get a little excited and shout, the ALC instantly adjusts the level to prevent distortion.

Either 115 or 230 volts is required for the power supply. An overload relay in the plate current circuit turns off the main power relay when plate current exceeds one ampere. An accessory dummy load is available which will take the full output of the transmitter for several minutes during tune up. A control knob on the front panel of the amplifier switches from the antenna to the dummy load; a thermal switch in the load will automatically turn off the amplifier if the load reaches it maximum rated temperature.

Collins 30L-1

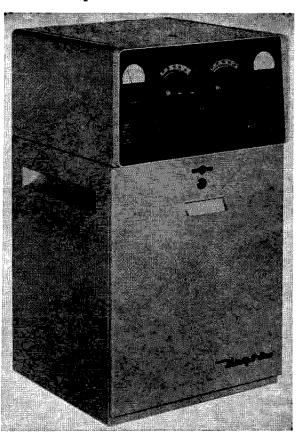

The Collins 30L-1 linear amplifier is rated at 1000 watts PEP on SSB and 1000 watts average on CW on all bands; it may be easily driven to its fulled rated input by any 70 to 100 watt exciters. This unit is completely self contained and designed for table top use.

Although the 30L-1 was designed specifically for SSB and CW service on the amateur bands from 3.5 to 30 MHz, provisions are made for general coverage use too. The ALC voltage from the 30L-1 linear is fed back to the exciter, providing maximum talking power without overdriving and distortion. In combination with rf inverse feedback, the ALC circuit provides more average power with a sharper sounding signal.

The 30L-1 uses four 811A triodes in the grounded grid configuration. Since the 811A's are instantly heated, there is no delay in warm-up.

In addition to indicating plate current and plate voltage, the panel meter is connected into a special comparator circuit. In the "tune" position, the amplifier is optimumly tuned when the tuning and loading controls are adjusted to zero the meter.

For safety, both the rf and power supply compartment covers operate safety interlock switches. Cover removal closes these switches and shorts the high voltage to ground. This arrangement protects the operator from accidentally coming in contact with the high voltage dc which is present in both compartments.

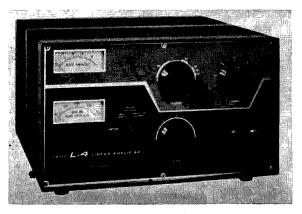

Collins 30S-1

The Collins 30S-1 requires only 70 to 100 watts of driving power to provide the full legal input of 1000 watts (average) on SSB and 1 kW on CW transmissions. This amplifier is completely self-contained and uses the commercially popular 4CX1000A as a grounded grid linear amplifier.

All the controls for operating the 30S-1 are conveniently located on the front panel permitting fast and efficient band changes. With the simple push of a button you can switch from the 100 watt power level of your exciter to the full kilowatt output of the 30S-1.

To assure maximum talking power and minimum distortion, the ALC voltage from the 30S-1 is fed back to the exciter. This, incombination with rf inverse feedback, provides a very clean and sharp signal. Correct tuning and loading are indicated by a zero reading on a full scale multimeter; the loading control and PA tuning control are simply adjusted to obtain zero meter indication.

Drake L-4

There's nothing halfway about the Drake L-4 linear amplifier; this unit is built for continuous duty at full capacity. The rating of 2000 watts PEP on SSB and 1000 watts on CW, AM or RTTY is ensured; the massive plate transformer, heavy duty tank components and voluminous cooling system make continuous operation at these ratings possible.

The power amplifier uses two 3-400Z or 8163 zero bias triodes in a class B grounded grid circuit. These two tubes have a total plate dissipation of 800 watts and their rugged construction will withstand a lot of abuse. For minimum distortion, higher efficiency and a constant 50 ohm input impedance, the cathodes of the 3-400Z's are matched with broadband tuned input circuits.

Any exciter that will deliver 100 watts PEP SSB and 75 watts on CW will drive the L-4 to the maximum legal input power. In the grounded grid configuration, most of the driving power is added to the output power. The use of a transmitting AGC circuit controls the exciter gain to allow a higher audio level without peak clipping. In addition, rf feedback is used to decrease distortion to better than 35 dB and tends to equalize tube characteristics from tube to tube.

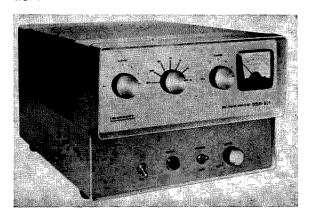

Galaxy 2000

The unique new design of the Galaxy 2000 permits the use of ten parallel 6HF5 tubes to deliver high efficiency, even on ten meters. In fact, the power output on all bands is guaranteed to be at least 1200 watts PEP. These tubes are easily obtainable and their total replacement cost makes them very attractive for linear amplifier use. In

the Galaxy 2000 the 6HF5's operate well within the manufacturer's voltage, current and temperature specifications.

The Galaxy 2000 operates in class AB₁ and delivers a very clean and stable signal. The amplifier incorporates both voltage and current monitoring, with an FCC specified time constant meter, as well as a tune position which monitors the rf output of the amplifier. The automatic linearity system (ALS) circuit used in the Galaxy 2000 provides automatic comparison of the inputoutput waveform, and acts on this information to maintain exact waveform duplication with best linearity.

The Galaxy 2000 features a compact table top design with built-in antenna changeover relay, heavy duty solid state power supply, and reduced power input in the tune-up position. Any exciter in the 100 to 200 watt class will drive the amplifier to full rated input and only a single ground of the operating control circuit is required for operation.

Gonset GSB 201

Exceptionally compact—only 8½" high, 12%" wide and 17" deep—the GSB-201 lends itself readily to table-top mounting. Finished in blending light greys, it presents a handsome, clean-cut appearance.

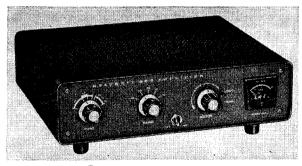

The Gonset GSB linear amplifier provides 10 dB gain on the 80, 40, 20, 15, and 10 meter bands with maximum input power of 2000 watts PEP on SSB, 1000 watts CW or 400 watts AM. It will operate with nearly any SSB exciter, homebrew or commercial; 100 watts PEP drive will provide the maximum of 1000 watts PEP output. The GSB 201 incorporates a number of desirable operating features which include the use of four low cost 811A tubes in stable, grounded grid circuitry. The power supply uses mod-

ern silicon rectifiers and an antenna changeover relay is built in. A panel switch permits preliminary tuning to be done at low power levels, thereby reducing interference. The plate current meter is switchable from the front panel to indicate plate current or relative power output.

Hammarlund HXL-1

The Hammarlund HXL-1 1500 watt PEP linear amplifier provides an excellent match to lower powered SSB exciters and provides 1500 watts PEP on SSB, 1000 watts on CW and 250 watts in AM service. This efficient linear uses a pair of 572A/B triodes in a bandswitching arrangement that covers all the ham bands from 80 through 10 meters. This amplifier features an internal power supply, built-in antenna changeover relay, pi net output circuit and a multipurpose meter which has been provided with a built-in circuit that even provides a linearity test.

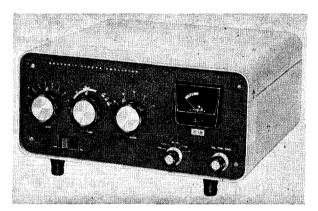

Heath KW Kompact

Interested in a kilowatt mobile? How about a small table top linear? The Heath-kit HA-14 KW Kompact may be just what you're looking for. This miniscule little box will provide up to 1000 watts PEP on all bands from 80 through 10, yet is only 3% inches high, a little over a foot wide and ten inches deep. It is small enough to be mounted under the dash of nearly any car

with plenty of room to spare-room enough in most cars to allow it to be stacked with your transceiver, providing a complete under-the-dash mobile kilowatt station.

Two 572-B/T-160-L's operating in parallel in the final provide a clean signal with third order distortion products 30 dB down at 1000 watts PEP input. A built-in SWR meter and antenna changeover relay add to the operating convenience. In addition, the broad band input circuits on each band require no tuning. Also, provisions for remotely controlling the power supply used with the KW Kompact should appeal particularly to the mobile operator.

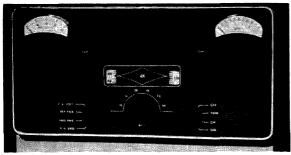

Heathkit SB-200

The Heathkit SB-200 desk-top linear amplifier is a complete self-contained unit that provides 1200 watts PEP input on SSB and 1000 watts on CW. This unit has its own built-in power supply and any exciter with 100 watts PEP output will provide adequate drive. Two heavy-duty 572-B/T-160-L final amplifier tubes provide an extremely clean signal with minimum distortion.

For maximum efficiency and low distortion, pretuned cathode input circuits are used. These, along with ALC within the SB-200 and provision for external use of the automatic level control result in a relatively constant audio output under varying conditions. The amplifier is completely shielded for TVI protection and stability and a builtin SWR meter and antenna changeover relay provide the maximum in operating convenience.

The conservatively rated power supply uses silicon diodes for maximum reliability and is circuit breaker protected (no fuses to worry about). In addition, this supply may be operated from either 115 or 230 volts ac, 50/60 Hz.

Henry 2-K

The Henry 2-K linear amplifier uses two rugged 3-400Z grounded grid triodes which were especially designed for zero-bias linear operation. These tubes provide 800 watts of plate dissipation and the full legal limit in all modes—2000 watts PEP on SSB and 1000 watts on CW, AM, and FSK.

The Henry 2000 watt linears are available in two models, the console model 2K-2 and the desk model 2KD-2 which has an external power supply. If you have your own power supply, the rf deck is available separately as the 2KR-2. The power supply used in these units is a heavy duty 2500 volt dc supply which is rated very conservatively. A choke input filter provides very good regulation and the solid state rectifiers insure year-in, year-out reliability.

For greatest efficiency and maximum attenuation of unwanted signals the pi-L plate circuit uses a silver plated tank coil. The band switch is a rugged unit with 20 ampere contacts and solid straight-through linkage. In addition, heavy duty bronze gears are used to drive the tuning capacitors. An aluminum cabinet eliminates any magnetic resonances and double rf shielding minimizes harmonic radiation. In fact, the second harmonic is more than 60 dB down from the full rated input.

To obtain maximum drive and maintain linearity, a resonant cathode-pi input circuit is used. The special plug-in design permits operation on any frequency from 3.5 to 30 MHz. The built-in SWR meter and rf output meter simplifies tuning up while allowing the operator to monitor the performance of his antenna.

In addition to the 2K line of linear amplifiers, Henry has just announced the new 4-K "Commercial" unit. The 4-K employs the 5CX1500A power pentode which is designed for superior linearity. This tube provides a full 4000 watts PEP input on SSB with efficiencies in the range of 60%.

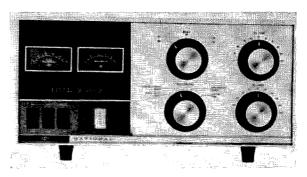

Hunter Bandit 2000B

The Hunter Bandit 2000B linear amplifier is designed for operation with SSB transceivers providing 100 watts PEP output. However, the output of the exciter may be substantially higher without harming the linear amplifier. This means that most modern SSB transceivers are compatible with the Bandit.

Four UE572B triodes are used in the power amplifier; these tubes provide 2000 watts PEP input on SSB. There is no warm-up period required because the filaments of these tubes are instant heating and the solid state high voltage power supply provides instant power. When the linear is turned off, the exciter is connected directly to the antenna through the internal antenna change-over relay.

A separate adjustable rf output meter is included in the output circuit of the 2000B. This meter permits the operator to adjust the measuring circuit to accommodate different feedline impedances and to adjust sensitivity on all bands. This meter is particularly interesting in that it follows the modulation envelope much like a VU meter and provides an excellent modulation monitor.

National NCL-2000

The National NCL-2000 covers all the amateur bands from 80 through 10 meters

and includes a husky built-in 115/230 volt AC power supply. The full key down power on CW, AM and RTTY is 1000 watts, with 2000 watts PEP on SSB for the full legal limit. The two 8122 ceramic tubes used in the final were designed specifically for single sideband service and provide 800 watts of plate dissipation to assure conservative operation. The output of the NCL-2000 is very clean with the third and fifth order distortion products down 30 or 45 dB respectively; in addition, hum and noise are more than 40 dB down and the full rated input.

The use of grid regulated class AB₂ operation results in high efficiency and linearity along with easy tune-up and low drive requirements; the NCL-2000 may be driven to full rated input with any exciter delivering 20 to 200 watts PEP. The NCL-200 is protected against overload and the operator against electrical shock with the built-in safety devices. In addition to fuses, time delay and plate current overload relays, a plate power lid interlock and automatic high voltage shorting bar are included.

Sideband Engineers SB2-LA

The compact SBE SB2-LA linear amplifier operates at 1000 watts PEP input on 80 through 20 meters and 750 watts PEP on 15 meters. Although the SB2-LA was designed as a companion unit to the SBE 34 transceiver, it will boost the output of any SSB transceiver up to a full kW PEP.

The input circuit of the SB2-LA uses a passive grid input circuit which offers a pure resistive load to the exciter. In the output a pi network provides matching to the transmission line with band switching from the front panel.

The built-in 115 volt ac supply is a voltage multiplying type unit; the high capaci-

tance filter capacitors provide excellent dynamic regulation. The low plate voltage—800 volts—is used with a relatively high current level. This arrangement is easier on the capacitors, rectifiers, power transformer and six parallel connected 6JE6's used in the final.

The SB2-LA has two built-in antenna changeover relays and internal blocking bias to prevent diode noise when receiving. For mobile operation the SB3-DCP inverter is available for powering the SB2-LA from a 12 volt source. The output of the inverter is 120 volts ac at 1200 watts; in mobile service the internal ac power supply is used.

Swan Mark 1

The new Swan Mark 1 linear amplifier uses two 3-400Z or 8163 zero bias triodes in a grounded grid circuit for convervative maximum legal input rating. A built-in power switch reduces the input to 1000 watts dc for CW and tune-up. The untuned input circuit provides the maximum in operating ease and permits very fast and wide range frequency changing.

The built-in 2500 volt solid state power supply may be powered from either 115 or 230 volts ac. It is very conservatively rated and the use of semiconductor rectifiers provides extended trouble-free operation. The tube cooling concept used by the Swan engineers guarantees long tube life and reduces initial equipment cost.

Dual change-over relays automatically switch the exciter in and out of the transmission line. The wide range pi-output network allows the Mark 1 linear to be used with a variety of antenna systems without the necessity of external matching networks. The metering of grid current, plate current, plate voltage and relative rf output permits monitoring of all the essential parameters and maximum tune-up ease.

Improved Electrical Connector for the Ham-M Rotator

After a Ham-M antenna rotator has been in use for several years, particularly in wet climates, the terminal strip at the bottom often becomes severely corroded and should be replaced. Rather than use another terminal strip which will have to be replaced in several years, a better approach is to install a waterproof connector. In addition to being waterproof and long lived, these connectors provide an extremely convenient method of connecting and disconnecting the rotator control cable when working on your tower. If you have ever installed a rotator, you know that connecting those eight control wires while you are seventy feet in the air is no mean task.

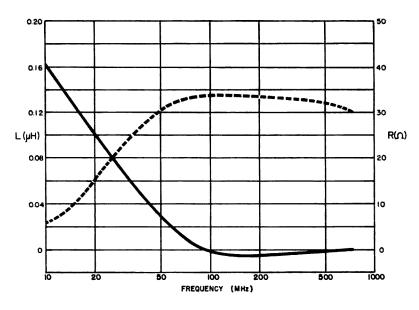

Two inexpensive connectors which are suitable for this job are the Amphenol MS 3106B-18-8S (cable receptacle) and MS 3102A-18-8P (chassis mounted plug). These connectors are available from Allied Radio Corporation* for \$2.40 and \$1.16 respectively. When ordering, specify stock number 47 D 7000C.

To install the chassis plug on the rotator, cut a small piece of aluminum the same size

as the old terminal strip and cut a hole in its center to mount the new chassis plug. Remove the old terminal strip from the rotator and carefully label each of the control wires (1, 2, 3, etc) with a piece of masking tape. Place the new connector strip in position and install the control the control wires on the new connector. The pins on the MS connectors are labeled with the letters A through H, so it is probably most covenient to connect wire number 1 to A. number 2 to B, etc. After the control wires are connected, install the connector mounting plate in the bottom of the rotator and attach it with screws through the original screw holes in the rotator housing. At this point it is a good idea to put some household caulking compound around the edge of the connector mounting plate to prevent moisture from getting into the rotator.

This scheme has been used several times and has proven to be particularly advantageous in wet climates or where ice is likely to collect on the rotator.

Ferromagnetic Beads

They say that good things come in small packages. And in case of ferrite beads, it's true. The Space Age and all that it implies has seen a reduction in the physical sizes of our components and some of our finished ham gear. Smallness for smallness' sake probably proves little, but when an inductor the size of a match head will perform useful tricks for us—that's handy news.

The beads have been around for a while but they haven't been readily available in amateur quantities until quite recently. The literature, similarly, has been pretty quiet on the subject of specific ham applications for this tiny component. It is most likely, then, that amateurs will expand the usefulness of these unique radioferric devices just as soon as they enjoy a wider circulation.

By simply slipping a bead over a 18 20 or 22 wire, an inductor is created. Going back to the basics for a second, we can recall that an inductor is an electromagnetic device possessing "self inductance" which is the quality of opposing changes in the current flowing through the circuit. This opposing action impedes the flow of the higher frequencies and can be assigned an ohmic value from the equation: $X_L = 2\pi fL$. When ferromagnetic matter is used as a core within or is posed near a coil, the reactive value of the inductor goes up as a nonlinear function of the permeability of the ferric material. Without plowing through the formulae, we can say that the Permeability Factor (μ) expresses the ratio of inductive magnification that a ferrous core will add to a plain wire inductor. For example, a toroid with a powdered iron core having a permeability factor of 10 will exhibit ten times the inductance as would the same circular coil with an air core. Meanwhile, back at the bead, we have a short length of wire having a certain small finite inductive value of its own. The addition of the bead, with a permeability factor of 900, elevates the inductance so that we have a localized high impedance point. The spectral usefulness of an Ami-Tron bead with mix "3B" is generally from 300 kHz through 300 MHz. As the frequency goes up, there is an attendant increase in the isolating ability of the bead.

The shielding action of a bead is due to the bead's offering a lossy medium to unwanted radiomagnetic influences within a circuit structure. Thus, stringing a wire with beads is a neat way to dampen rf feedback

73 MAGAZINE

paths that often result in either obvious or subtle parasitic effects. As we have all had occasion to witness, the feedback pick up is greater in high impedance circuitry. Grids and gates are sitting ducks for strong rf fields. In practical terms, the thing to do is to slip a bead or three over the wire connecting to the base, grid or gate. In printed circuit work, the beads should be threaded over the element lead between the semiconductor case and the circuit board. It is not necessary that the beads be grounded.

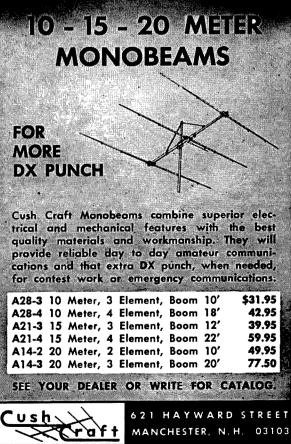

It is unlikely that ferrite beads will completely replace the ubiquitous 2½ mH rf choke, but they do offer some attractive decoupling qualities. When a bead is placed on the conductor leading to or from an active rf circuit, we have, in effect, a miniature rf choke. Its inductance may be in the order of a few nanohenries, but at VHF this can be very useful; and the simultaneous bulk shielding action is pure serendipity.

In addition to the suggestions contained in the Ami-Tron spec sheet, it is to be expected that ferromagnetic beads will find themselves being used by hams in ways that are limited only by the imaginations of the users. Consider the case of the hard to cure key click, or TVI, that develops in a sharply tuned Class C amplifier that is trying or succeeding in its efforts to go into business for itself as an oscillator. Unneutralized tetrodes such as the old work horses 813 and 807 are famous for this stunt. The spectral garbage that results usually fails to respond to the more general handbook nostrums and an operator can spend whole week ends decoupling nearby innocent circuitry. It sounds a little David And Goliath, but one bead on the right tetrode G1 could do the trick. It is just a question of time until some VHF man will make a space saving Pi-Network consisting of two capacitors and one bead. I'm anxous to try some beads between the suppressor grid and ground on a couple of sluggish pentode if stages. The mild regeneration created by this amount of decoupling should narrow the pass band and bring up the gain. But first, there is the matter of weaving a few beads into the crystal mike circuit to get rid of that rf feedback for good, this time.

. . . W6SFM

A package of 12 ferromagnetic beads is available for \$2 from Ami-Tron Associates, 12033 Otsego St., North Hollywood, California.

A Canadian Assault on FP8

Geoff, VE1UC, walked up to the ticket counter at Air St. Pierre and asked for three tickets to the island. The young lady at the counter gave us our tickets and boarding passes and sent us to check our baggage. Arriving at the baggage counter, the same young lady checked our bags, and at yet another counter she collected our overweight payments. As we climbed on the venerable DC-3 she accepted our boarding passes. With a polite inquiry as to whether or not she would spin the props as well ("oh no, M'sieur, they are electric-starting!"), we settled in our seats, buckled on our French accents, and were off.

This episode, on August 1, 1966 marked the end of four months' preparation for the first VE1 expedition to FP8 land.

Don, VEIAMC, and myself, VEIADH, had driven up to Sydney, met Geoff, and now the three of us were finally in the air—hoping the fog had lifted over St. Pierre, and wondering if the book the pilot was reading was a DC-3 operation manual. Snuggled in the cargo hold was an SX111, FL100B, and Gonset 6-meter rig—all packed "lak eggs, yes?" against the whims of French cargo-handlers.

Some two hours later we arrived over the island. For miles around visibility was unlimited—no difficulty at all in seeing the vast fog bank sitting off the coast of St. Pierre. Our hearts sank lower and lower. Small wonder, our stalwart birdman was coming in for a landing—the runway was ahead—a hole in the fog—and we're down! "Say, Don, how did we ever miss those fishing shacks? Oh, well.

The runway on St. Pierre is dirt, and pretty short—so much so that when taking off the pilot makes a sharp left bank immediately upon liftoff—to avoid those fish-

ing shacks! At one end of the runway is the smashed remains of a DC-3, which boobed up a landing—and at the other end, a similar corpse marks a poor takeoff—"Ah, but m'sieur, those planes do not belong to Air St. Pierre—our predecessors, you know". Our faith restored in our pilot (we had to fly back, y' know), we set about rescuing our bags. The cargo-handlers looked very competent and we had utmost faith in their ability—we only helped them unload our gear for the exercise!

Having cleared customs, and paid our \$1 landing fee, we discussed the best way to get over to our hotel. "How's your French?" seemed to dominate the conversation for a spell. Finally I took the bull by the horns, walked up to the nearest gendarme and said "Gus Roblot?" (FP8AP was our contact on St. Pierre). "Aha", says the gendarme, breaking into a smile, "les radio-amateurs!" That's the magic word on the island-we weren't tourists, but radio amateurs! A world of difference! Off to the telephone-Gus is summoned, and soon arrives in a venerable stationwagon. Gus-a Frenchman's Frenchman-and one darn nice guy. He was indispensable to us, and anybody planning a trip to FP8 should write him. Life is so much simpler with an interpreter.

We were soon at the hotel, our bags deposited, and assured that our license would be forthcoming tomorrow. We set up our station, strung up our antennas, and went out to see the town.

St. Pierre looks very similar to any fishing village found on the Nova Scotian coast, and I commented to Don as we walked along that it didn't seem to be "a tiny Paris"—but our opinions changed very quickly. The main part of the town looks over a large square situated on the waterfront. Tourists

86 73 MAGAZINE

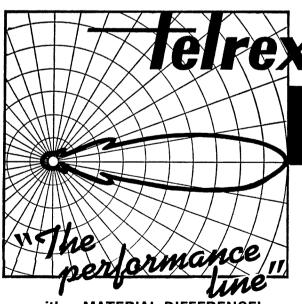

abound: fishermen are tending their nets, grandmas are sitting in the sun, mothers walk their babies—and on a park bench in the middle of the square, at 2 P.M. in the afternoon, this French couple is making out like nothing you ever saw in any French movie! "Sydney was never like this!" exclaimed Geoff. As we headed for the nearest outdoor cafe and our first taste of FP8 hospitality, we were prone to agree.

A work about this hospitality—it's terrific. The people are friendly and go out of their way to assist "les radio-amateurs" in every way. We had two rooms side by side, with a total of three beds, and this, with three meals a day cost each of us \$6.80 per day at the New Royale Hotel. Madame Miller was an angel, and couldn't have been nicer, even at 3 A.M. one morning when Geoff and I rolled in showing the effects of the local lightlife. The food was delicious and the wine was on the table for every meal (even breakfast!).

The following day we were picked up by Gus and went off to collect our license. We soon returned—proudly bearing FP8DA, and away we went. Lots were drawn for first QSO, and VE1AMC fired up on 20 CW and shortly raised VE3GEG in Georgetown; next was WB2PXU, WB2JJF, WB2GKZ, and from then on we were working one every three minutes. With half the bank calling us, we took shifts operating and

logging, and soon became quite adept at switching ops in the middle of a QSO.

Don had set his hopes on a 6 meter opening, and we had a dipole on the hotel roof. At 2030 GMT I tuned in on 6 (we were monitoring during the entire week and heard CO-the W1V1A/1 calling band opened! I grabbed the mike and called: "W1V1A/1, here is the French island of St. Pierre, FP8DA, calling on 6"-"what did he say that call was? F-something? Give me that again, OM" (a tremor of excitement in his voice), "WIVIA/1, here is FP8DA, FP8DA, on St. Pierre Island, how copy?" "I'll be FP8DA on some island-this is W1VIA/1 . . . where are you guys? . . let me write this down . . ." Fellas, it was beautiful. You forgot our call, you forgot your calls, you signed after our transmissions without giving us RST and QTH-I never heard such excitement. The whole opening was calling FP8DA. and that hour's opening made the whole trip. We worked 50-odd QSO's in 9 states, and never had so much fun in our lives. I'll never forget sitting on the bed about half-way through the opening. At one end of the room sits Don, peeling off QSO after QSO, on 6, and muttering . . . "Spread out fellas, don't all call at once . . . where did they all come from?", while at the other and Geoff is working one a minute on 20 CW and singing . . "They're coming

to take me away, ha ha, ho ho, hee hee . . . "

About 9 P.M. we packed it in, and went out to explore the night life. We soon discovered that drinks were \$.40 a piece. (\$.50 if you asked in English). The drinks were all three fingers apiece, and if you wink at the bartender and say "Un peu aussi, s'il vous plait" he splashes in another finger or two. Canadian or American currency is accepted, and Geoff and I managed to get utterly stiff on \$2 every night we were there. Don, who doesn't indulge, kept the fires burning on 20 at night, and tucked us into bed when we managed to find our way home.

A few incidents which took place during our stay:

I was dancing half one evening with a pretty young miss, struggling the while to make a favorable impression while cursing my despicable French: finally, after a particularly frustrating session while I tried to explain how fast my green Triumph would go, she ups and says "You know, your accent really is terrible!" Turns out she is a University of Toronto student studying French on the island!

One evening Geoff and I are walking along a street in town when a very distraught woman, very obviously an American tourist, runs up waving her arms and wailing that she was lost-couldn't speak French-and ". . could you nice boys tell me how to get back to the boat?" Geoff, who was wearing his beret, puts on his bon vivant look and says "Pardon, madam, je ne parle pas l'Anglais . . . parley-vous français?" tourist gave him a dirty look and walked off muttering something about "another one". Another time we were on a bus waiting to go to a roadhouse outside of town, while some chaps from an American sailboat debated if they should go. Our bon vivant, avec beret, leans out the window and growls "Messieurs, le Savoy, tres bien. Venez avec moil". The lads trooped aboard, and ended up as looped as any. I think it was Geoff kissing his fingers and winking that got

Wednesday night Geoff and I arrived home in the wee sma', somewhat cheerful—to find Don and some stranger ensconced in the shack in front of a SB100 hooked up to our antenna, and killing them on 20 SSB. Turns out that John and Shorty, VE3EWM and VE7AZ had arrived that

evening for a few days. Anybody who worked FP8DA that night after we arrived may have wondered at the strange noises in the background—it was Geoff and myself being suppressed by Don so John could work new countries for FP8DA. The next day the boys received FP8DB, and provided us with a new country (St. Pierre, what else?)

The rigs worked FB, except for a melted pi coil on the second day. We left the transmitter out of the case after that and spent the evenings watching a room across the road increase in light intensity by a factor of 3 each time we pressed the key. The T.V. watcher never did complain (wonderful people!), but expressed his ire by heaving the occasional rock at the hotel wall. We could gauge the programs he enjoyed most by the "thump frequency".

Toward the end of the week VE1TG, George, and a chum wandered in, and we also had a visit from FP8CY. We all sat down to supper together one night, and by the time the second bottle of wine arrived we were into a real hamfest.

The Sunday following, we packed up our gear, rescued our antenna tuner from FP8DB, and folded our tents. With a last "au revoir" from Madame Miller, our fingers crossed against the fog moving down off the mountain, and a prayer that the pilot wasn't at that last party, we boarded the DC-3 and silently stole away.

Statistics? We had 700 QSO's, worked 34 states (9 on 6 meters) and 33 countries. The trip cost each of use \$150 (including plane fare) for the week. The weather was warm most of the time, the wine was sweet and so were the gals. The thing that impressed us the most was the proficiency of the French drivers in survival; traffic control on the island consists of beeping as you enter each intersection, the theory being that if you hear another beep, you've had an accident.

Anybody planning a trip is urged to write Yvon Segineau at the Bureau de Radio Communications on Saint Pierre well in advance for licensing info. They are stiffening their procedures, and licenses will not be issued as casually as in times past.

We all enjoyed the trip tremendously, and unanimously invite you all to join us when we hit the beach again next summer. Return, you ask? Mais oui, messieurs! Au certainement!

. VE1ADH

"Get-Acquainted-with-Sideband" offer

During the course of any given week, I meet several hundred hams and as a result of these experiences for the past several years, I feel I can interpret what the average ham is looking for. Our business is, therefore, geared to supply the hams the items which they want and which they can afford to buy.

In consequence of the approaching 11-year sunspot peak, 5-band transceivers are literally selling like hot cakes, and hams who heretofore have been happy with a 3-band model have been trading them in at a relatively high rate. We think this is sound business but now we have the problem of marketing these excellently designed 3-band sideband transceivers. As an example, as I write this ad, we have in stock 36 National NCX-3's. This very popular device is rated 200 watts input for sideband, 200 watts on CW, and 100 watts on AM. It will provide 120 watts RMS out. It will match any coax fed antenna between 40 and 60 ohms impedance. It covers a frequency range of between 3480 and 4020 KC on 80: between 6980 and 7310 KC on 40; and between 13880 and 14420 KC on 20. The band width is 21/2 KC. Sideband generation is by means of a 5200 KC crystal filter. The overall drift is negligible—not exceeding 400 cycles after 15 minutes warm up. The unwanted products are down 40 db; the carrier down better than 50 db. The NCX-3 uses 18 tubes and 16 diodes. Mechanically, it is 61/16" high x 13%" wide x 11%" deep and weighs approximately 15 lbs. net.

We offer re-manufactured NCX-3's. (This is our term for a set that has been exhaustively checked out and which is impeccably clean), together with a choice of power supply combinations at what I honestly believe to be the lowest price in the nation. Listen to this. We will provide the NCX-3 together with a kit of power supply components for only \$250 f.o.b. Harvard. This breaks down to be better than \$82 per band, a lower price than any comparable offering made even for a kit on a tri-

band set.

Our power supply is a universal sideband transceiver power supply which furnishes between 800 and 1,000 volts for the final, between 250 and 320 volts for the exciter stages and the receiver, 12.6 volts of AC at 61/2 amps, 14 volts of DC for relays, and bias of up to minus 100 volts at 100 mils. We furnish the chassis, the bottom plate, and even a matching speaker and proper plug for the NCX-3. We furnish all of the components except the hardware with which you can mount the pieces. We tell how to build this supply. This supply weighs better than 40 lbs. when finished. It is a rugged unit. The transformers weigh in excess of 17 lbs. There are heavy, rugged parts employed in every circuit. We use, for example, four 400 mfd capacitors. As another illustration, we furnish twelve 800 volt diodes. You can build this supply in one evening and be on the air the second evening.

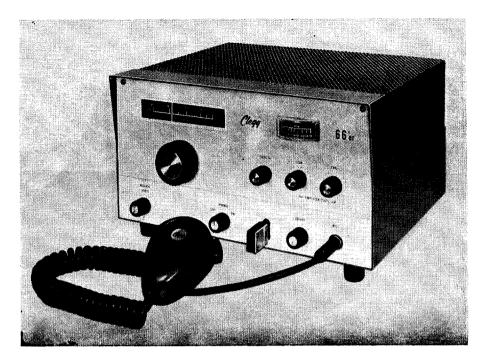

If you are one of the boys who as yet has not tried sideband—and you are now looking for an excuse to break in at an inexpensive price, here is your deal. Best of all, the power supply we furnish will allow you to subsequently operate any of the standard transceivers made today including Swan, Drake, Collins, Hallicrafters, and National. There would be no need, for example, to buy a second power supply in the future. We guarantee what we offer and this is, practically speaking, one of the very best buys that we have ever offered to the American ham. Trades are acceptednaturally; time payments are available for those who have credit. This offer is limited, however, to the extent that our stock shall last. Remember, you get an instruction book on the transceiver and on building the power supply and that you can operate 3 bands-CW, AM, or sideband—for only \$250. We offer the same deal with our power supply wired by our own boys for only \$50 more. In other words, \$300 will buy a package that you can plug in when you get it.

The Clegg 66'er Six Meter Transceiver

Interested in 6 meters? The Clegg 66'er from Squires-Sanders does an outstanding job and is an ideal rig for the ham who operates on our 50-MHz band. This transceiver contains a stable and sensitive receiver and a 22-watt transmitter in one compact package. It was designed specifically for the six meter band and will cover the amateur frequencies as well as those for MARS, CAP and Civil Defense. In addition, both the 117 Vac and 13 Vdc power supplies are included in the package.

The dual conversion superhet receiver is extremely sensitive and less than $0.35~\mu V$ signal will provide a signal plus noise to noise ratio of 10 dB. The basic frequency range is 49.9 to 52.1 MHz, but for special applications, an expanded tuning range is available on special order. The two *if* frequencies of 10.7 MHz and 456 kHz provide 8 kHz selectivity and result in rejection of spurious responses by more than 60 dB.

The receiver is relatively straightforward with a 6EH7 in the front end, followed by a 6DJ8 converter to the 10.7 MHz if and a 6BA6 if amplifier. The injection frequency for the first conversion is provided by a 6KE8 VFO/buffer; this combination is quite

90

satisfactory and results in less than 3 kHz drift per hour after a 20 minute warmup. The 10.7 MHz *if* signal is converted to 456 kHz in a crystal controlled 6BE6 converter and further amplified in another 6BA6 stage, followed by a 12AL5 detector, a 6AN8 audio amplifier and a 6AQ5 audio power stage.

The AGC voltage generated in the 12AL5 detector stage is applied directly to the two *if* amplifiers and the 2nd mixer and through a Zener diode to the rf amplifier; in this way no AGC is applied to the input stage until comparatively large signals exist. The other half of the 12AL5 is connected as a series gate impulse limiter; it is very effective in cutting down ignition and other types of impulse noise.

A semiconductor diode is connected as a series squelch diode between the output of the detector and the input to the first audio stage. Whenever the cathode of this diode is more positive than the anode, the audio sections of the receiver are effectively disconnected from the front end of the receiver. Since the anode of the squelch diode is connected to the screen voltage of the

6BA6 456 kHz if amplifier through a decoupling network, the voltage on the anode varies automatically as the screen voltage follows the AGC level. The cathode of the squelch diode is connected to a voltage divider across the B+ supply; the cathode voltage (and therefore the squelch level) is set to the desired threshold with a potentiometer in this divider.

No tricks in the transmitter section of the Clegg 66'er either; time proven circuitry starting off with the triode section of a 6KE8 in a Colpitts type crystal oscillator. The 25 to 26 MHz harmonics of this oscillator are coupled to the pentode section of the 6KE8 through a bandpass coupler; this pentode is operated as a frequency doubler to 50 to 52 MHz and is bandpass coupled to the 12BY7 driver stage. Considerable reduction in undesired outputs is obtained by using bandpass coupling and straight through operation of the six meter driver

In the final rf power amplifier, a 2E26 provides 13 watts output with 22 watts input, an efficiency of 59%. This final stage is plate and screen modulated by a pair of 6AQ5's. By carefully choosing the design constants in the modulator circuit, high frequency splatter components are completely filtered out. In addition, the operating level of the 6AQ5's was chosen so that grid clipping and plate bottoming occur at approximately 10 watts audio. Therefore, overmodulation is prevented while providing effective speech clipping at the 90 percent

The triode and pentode sections of a 6AN8 are used respectively as a microphone amplifier and audio driver. The pentode actually does double duty in the 66'er; in the receive mode it operates as an audio amplifier.

One of the big advantages of the Clegg 66'er is the built in power supply which will operate from either 117 Vac or 13.8 Vdc by simply plugging in the correct plug. Furthermore, either positive or negative ground de systems may be accommodated by a simple rewiring job. The versatility of this power supply is a direct result of the two winding transformer which it uses; in the ac mode, the 117 Vac is connected to one of the two primary windings on the transformer. In the dc mode, the 13.8 Vdc drives a two transistor inverter which is connected to the other primary winding.

The Clegg 66'er transceiver is one of the most versatile six meter transceivers that this reviewer has seen. It fits right in with fixed station operation, mobile operation or even for mountain topping during VHF contests. And-if you're not satisfied with 22 watts input, you can always plug it into the Appollo linear. Zingo-675 watts de! ... W1DTY

CLEGG "66'er

transceiver complete flexibility—built-in dual power supply for 115 VAC or 12 VDC, compact size make it ideal for mobile, fixed or field use. Loud and clear reception—highly sensitive and selective dual conversion receiver offers great freedom from birdies, tweets and spurious signals. Front end design provides superb signal capture, freedom from cross modulation and overload. High Talk Power Modulation is achieved by an effective 22 watt input transmitter, with speech clipping. For a clean 70-75 watts output, combine the "66'er" with the powerful Clegg Apollo Linear Amplifier. Built-in S-meter serves as tune-up meter for transmitter. The spectacular new 66'er is great for hams, CD, MARS and CAP operators. See Clegg and Squires-Sanders communications products at your dealer. Write for literature today to:

Squires Sanders

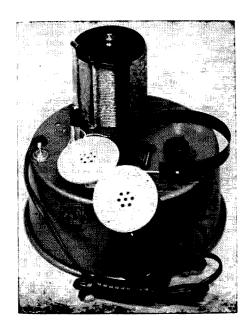

Morse Code a Stumbling Block?

If you were once a Boy or Girl Scout and had to learn morse, do you remember how you did it: A is dot-dash; B is dash-dot-dot-dot, etc-phonetically? Or even if you used a key and a buzzer it was by memory of the dits and dahs, rather than by the group sounds of the characters as in the case of speaking words.

Trying to remember the dits and dahs as simply dits and dahs has a natural limitation at the point where you require too long an interval to say to yourself: that was F or Q, etc., because the first or second dit or dah of the next leter has been sent and you have missed it while trying to identify the preceeding one. If you had to do this when listening to others talking—hesitate after each word to figure out what the word meant, what a dull conversation would result. Think how long it would take to get a reaction to a joke!

For people who have learned the individual dits and dahs it takes a long time to break through into the group-character areashort words, then longer words and real fun with code.

There is at least one method available by which you can speed up your code learning, a method which has proven itself over the years to be superior to others. This is the "Teleplex" method. Teleplex is a code sending machine using metal rolls instead of tape, so they never wear out, which is fully adjustable in speed, emitting a 750-hertz tone which seems to be the best tone at

which the ear begins to get the dit-dah sounds as groups and words. Loud, high pitched tones apparently create unrecognized echoes which interfere with the recognition of group sounds, slowing down the learning process.

The Teleplex theory emphasizes first the 750-hertz, which cannot be varied, and second that the student should know in advance (during the early phase of the course) what words are coming, so that instead of trying to pick out the individual letters he will become conscious of the letters as group sounds in their naturally rythmic relationship, as is the case with the words you speak. Also, Teleplex permits a gradual almost imperceptable, change in speed, so that rather than trying to copy 5 wpm faster than you can now copy, you can increase the speed by fractional wpm and not be under such strain. In this way you can continue to recognize the word groups, rather than jumping into a speed where the groups are indistinguishable.

Teleplex can be purchased or rented. Write them at 739 Kazmir Court, Modesto, California.

The Little Gem Fuse Tester

The Little Gem Fuse Tester.

Here's an oldie that we haven't seen around for ten or fifteen years. There are several versions of this little first-day-of-April gadget. Ours calls for a neat little Minibox, a nice big bull's eye pilot light (110 volt variety), a fuse in its holder, a push button, a spare fuse container with spare fuses, and a cord with plug. See the photo.

On ours we put the title "Little Gem Fuse Tester" on a plastic label at the top. In the center we put "If lamp lights, fuse is good". There is no label on the push button. Everybody has an uncontrollable urge to push a button. If you push the button, of course the fuse is blown and the light goes out.

Schematic of the Little Gem Fuse Tester.

There are several approaches to the use of this "Little Gem". One way is to simply lay it on an associate's desk or work table. He will probably come in pick it up, plug it in, and try it out. As soon as he realizes that he has been had he will put it on the next person's desk. . . The spare fuse container may have to be refilled a time or two during the day. One variation is to leave out the fuse, in which case the building fuse blows and possibly the lights go out. Some administrative personnel may take a dim view of this!

In our case we made out a very official interdepartmental memo stating that we needed some lay experimenters to determine the value of the device. Then on a second sheet (not to be read previous to experimenting) we put a bunch of questions like "Was the fuse good?", "Is it still good?" etc. leading up to a "Happy first day of April to you".

You can have a lot of fun with the "Little Gam Fuse Tester".

. . . W7CSD

What's New for You?

This column is devoted to short, timely items of interest to technically-minded hams. We'd like to cover new semiconductors and other components of special interest, new surplus, technical meetings, clubs and nets, comments about 73 articles, and so forth. All will give credit to the submitter. Please get all items in as soon as possible so that all readers will be able to take advantage of them. Keep them short, please. Send to: What's New, c/o Paul Franson, 38 Heritage

Rd., Acton, Mass. 01720.

MODEL 400 AND 501

TV CAMERAS

From \$125.00

Each month we have a limited quantity of used TV cameras which we make available to hams at greatly reduced prices. Some cameras were used as demonstrators by our salesmen; others like our Model 400 were traded in for our 501. A few are back from being rented out on special temporary surveillance jobs. Some were modified slightly to fit the particular job and may have extra holes or vary slightly in appearance from the photos. All have been checked out and are guaranteed for 90 days. Complete with vidicon and lens.

Model 400 sale price \$125.00 FOB Hoilis Model 501 sale price \$160.00 FOB Hoilis

These used cameras are for sale to radio amateurs only. Include call letters with your order.

DON'T DELAY. ONLY A FEW ARE AVAILABLE EACH MONTH.

For specifications on the 501 see our other ad elsewhere in this issue. For specifications on the 400 see 1965 issues of 73.

Technical Aid Group

The first members of 73's Technical Aid Group are listed below. They are willing to help other hams with their technical problems. If you have a concise question that you think can be answered through the mail, why not write to one of the hams on the list? Please type or write legibly, and include a self-addressed stamped envelope. One question to a letter, please.

If you'd like to join the Technical Aid Group and you feel that you are qualified to help other hams, please write us and we'll furnish complete information. It's obvious that we need many helpers in all parts of the country and in all specialties to do the most good. While 73 will try to help with publicity and in other ways, we want the TAG to be a ham-to-ham group helping anyone who needs help, whether they be 73 readers or not.

Hildreth Press

The changeover in printers has gone extremely smoothly and our old printer has been most cooperative in getting all our materials out to the new press in Illinois. Changing printers is a tremendous undertaking for a magazine because printing schedules are upset, huge amounts of material must be moved and accounts must be closed out. Hildreth Press, our previous printer, put forth a great effort and took care of everything smoothly and efficiently; in a matter of days our new printer was all set to go.

And then the biggest snowstorm in fifty years paralyzed the Illinois area; traffic came to a standstill, the pressmen couldn't get to work and little, if anything, was getting in and out of Pontiac, Illinois, including 73 magazine. Finally, however, the February issue hit the street. It will take us several months to make up the time lost because of the storm, but by cutting a little off the schedule each month, we hope to be completely back on schedule by the time you get the June issue.

Jim Fisk W1DTY

Aligning Decals

Having trouble lining up decals or dry transfer labels on that new piece of equipment? Without some kind of aid, it's a little tough to line up the labels on a panel and make sure that they are all parallel. One of the easiest ways to do this is to stretch a rubber band around the panel and align it with a ruler; all the decals placed along the rubber band guide will be perfectly aligned. This system has the advantage that no alignment marks are left on the panel after the labeling is done.

Climbing the Novice Ladder

Part V: A stroke of luck for Judy

On the Wednesday following their last session at FN's shack wherein Larry and FN put Judy and Joe through an informal preliminary verbal exam, the kids toured the local ham supply stores in search of a receiver for Judy. At all three places, they unearthed several used receivers of conventional ham manufacture as well as a couple of the Command type of military surplus. With one exception, none of them seemed to quite fit the picture. Some were priced considerably beyond Judy's budget, a few were in somewhat questionable 'as is' condition and the Command sets, although moderately priced, would both require more extensive modification than desirable for a beginner. However, at Daly's Ham Shack they found a little Conar Model 500 novice receiver kit which had been 90% completed only 11 steps remained to be accomplished. Tim Daly explained that the young fellow who had purchased it initially had just been inducted into the military service and had left for duty before he could complete it. He had left the little rig with Tim to dispose of for him. The previous workmanship appeared to be neat and substantial and that remaining to do did not appear to be too difficult of accomplishment. Tim was offering it 'as is' at the very attractive price of \$20.00 which would not take too many spareribs from Judy's piggy bank. Tim agreed to hold it until Judy could talk to FN and get his opinion.

That same evening Judy's Dad agreed to drive her out to FN's place. After explaining briefly what she and Joe had found at the various stores, Judy said, "Gramps, both Joe and I think the little Conar would be a pretty good bet. I'm sure I could finish it and it's well within my budget. Joe phoned me just before I came out here tonight and said he'd run into Larry at the gas station and told him about it. Larry knew the guy who had started building it and had seen

the job. He told Joe that it sounded like a pretty good deal to him but to talk to you about it first."

"Well Judy", replied FN, "you say there are but 11 steps to complete in the instruction manual. I've got a Conar manual here, let's see what these really amount to". So saying, FN reached into his filing cabinet and pulled out the assembly and wiring instructions. Counting back 11 steps he said, "Actually this involves only installing and soldering in place five relatively simple pieces of wire. The other six steps have to do with the adjustment and alignment procedure. This, you'll remember I told you and Joe awhile back, is not always as easy a procedure as it may appear to be on the surface. The Conar is a straight superhet which is of course, desirable for selectivity and sensitivity. The schematic is conventional and with proper instruments, the alignment should be relatively simple as the adjustments seem to be well detailed in the book. I've got suitable test equipment and if we deecide this to be the rig for you, we can all get together here on my bench and bring the little chick to life. Let's do this; I've got to go to town Friday so suppose tomorrow I call Tim Daly and ask him to hang on to it until I come in and I'll have a look at what's been done and what's to do. After I give it the eagle eye, I'll give you a definite 'yeah' or 'nay' . . . what say?"

"Oh fine, Gramps, I'll really appreciate it and if you say go I'll pick it right up and we can get busy on it".

As FN nodded agreement, Judy's Dad surprised them when he said, "Say FN, if Judy goes for this little receiver, mind if I come along when she works on it? I'm gettin' kinda interested in this ham stuff myself after listenin' to the kids drone away with that code hickey they've got out in my storage shed".

98 73 MAGAZINE

"Well, blow me down, Tom," replied FN, "I never thought the radio bug's stinger was long enough to penetrate that tough old carpenter's hide you walk around in; sure thing, drag yourself right along if Judy gets going on this and bring Edna with you . . . she and Ma can swap valley gossip while we're cluttering up my bench . . . glad to have you".

True to his word, FN called Tim Daly who agreed to hold the little receiver until FN dropped in on Friday and checked it over. His inspection indicated that while perhaps not exactly a professional job of workmanship by the previous builder, it was substantially done, connections well soldered and the general assembly indicated that care had been used throughout. Telling Tim that he would give Judy the green light on it. FN finished his errands in town stopping at Judy's place on the way home and giving her his decision. Her Dad was busy with a kitchen drain board job on the other side of town but Judy was sure that he'd take her to town in the morning and pick up the Conar. FN invited her to bring it right out to his shack then if she'd like to get started on it but first he cautioned her not to neglect her study of the examination material reminding her that the following Saturday both she and Joe were due for their formal code exams and shortly thereafter, the written portion. "Oh, I won't Gramps; I'm still reading myself to sleep with the books every night and I've got code, rules and regulations practically running out of my ears" she laughed.

That evening, Joe phoned Judy to check on progress and she invited him to join her at Tim Daly's in the morning and they'd pick up the receiver and he could accompany she and her Dad to FN's and get in on a bit of the final completion of the little rig. Joe eagerly agreed and both kids looked forward with eager anticipation to an enjoyable session on FN's bench.

As Judy had surmised, her Dad readily agreed to take her down to Daly's, pick up the receiver and then out to FN's shop, so the next morning Judy cranked the tail of her piggy bank until it had spewed forth twenty of the closely hoarded dollars from her summer odd jobs. Tom Mansfield backed the station wagon out of the garage and they took off for town. Joe was waiting so it was but a matter of minutes to empty her poke into Tim Daly's hand, take a re-

ceipt, pick up the little box and head for FN's. They stopped by Judy's place to pick up her mother who would visit with FN's XYL while Judy and the men folks delved deeply into Pandora's electronic box.

FN started the session with, "All right now; you kids take the assembly manual, figure out the five wires you will still have to install and get them placed and soldered. Tom, you hang over their shoulders and soak up a bit of this stuff . . . you asked for it you know and you'll soon see what you've let yourself in for". FN chuckled and continued, "I'm going to be clipping the hedge out back; when you're through with those wires let me know and we'll lay out the test gear and go through with the alignment."

Some forty five minutes later both young-

Judy and Joe went shopping for a receiver for Judy.

sters were satisfied that they had it finished and Joe went out and rounded up FN. He too considered the wiring satisfactory and announced, "We've reached the point now where we're ready to give it the initial 'smoke test'; you know, plug the cord into an AC outlet, turn on the power switch and 'tune for minimum smoke' . . . go ahead Iudy". Somewhat dubiously she was about to gingerly push the plug into the outlet when FN stopped her with, "Uh uh, Judy; check your panel switch first and be sure it is in the 'off' position; always do this with any piece of gear before you plug it into a power source. Just like your Dad's FM radio, the power switch here is part of the volume control; click the pointer to the 'off' position. That's right, now plug in the power cord". This done. FN carefully scrutinized the chassis for a few moments then said, "No smoke; so far so good. Now click the power switch to 'on' and let's take another look; good, the little panel indicator lamp glows and we blew no fuses. All of the tubes show a normal dull glow inside their envelopes so apparently all heater circuits are correct. Now advance the volume control slowly clockwise; the tubes should be warm enough now to produce some background noise in the speaker. Yep, there she comes . . run the volume clear to maximum; the background increases normally as you go . . fine. Turn the volume back down a bit now and just let her set and 'cook' while we haul out the test gear for alignment; we'll use a signal generator and a vacuum tube voltmeter for these final steps". Just then FN's XYL announced lunch for all hands on the patio and, at FN's direction, Judy turned the power switch to 'off' and pulled the power cord from the outlet. "Better we get a bite or two under our belts then we can come back and go right through the final steps without interruption" and, after washing up, the 'junior scientists' joined the oldsters at the picnic table.

After bountiful replenishment of the body fuel, FN stoked his trusty briar and when she was drawing well, sleeves were figuratively rolled up and the curtain was ready to rise on the final act. "Here's the test equipment, kids; Joe knows how to use it from his class work; the book tells you just what to do with it, where to connect it and how to use it. I'm not going to say a word; simply follow the instructions and I'll stand

by in case you hit a puzzle or two. Tom, you can watch, but don't touch; you're not going to sneak into the ham hobby by jumping into something right in the middle like this. If you get serious about this ham business you're going to have to start from scratch like the young 'uns did. Ok; get going kids".

Step by step with an occasional question to FN to clear a doubtful point, Judy and Joe worked through the various tuning slug adjustments. At FN's suggestion, each would carry through one step and the other would repeat the process as a double check before proceeding with the next. They discovered that meticulous care was necessary as they proceeded; many of the adjustments were sufficiently critical that the peak performance point could be easily passed over. Obviously alignment was not a procedure which could be handled on a hit or miss' basis with any expectation of realizing the full potential of a receiver. Ultimate performance could be reached only by devoting plenty of time to careful adjustment and simultaneous checking of meter indications. At last however, the final screw had been turned, a re-check of some of the operations performed and with a couple of relieved and profound sighs, tension relaxed. "Well, Gramps, what you think?" queried Judy, patting her copper-hued locks back to some semblance of a girlish hair-do.

FN smiled and said, "Bravo! There were a few times there along the line where I was tempted to shove in my two-bits worth but I decided to let it ride. You've done rather better than I had expected and you have the little rig in pretty fair shape right now to drag in a pretty good assortment of signals . . let's see if it will. Tom, I'll relax a bit and let you stick your finger just a little way into the pie. Disconnect the test leads . . . ah, ah . . . remember to pull the AC plugs first . . . and set the test gear to one side. Now take these two clip leads and connect the antenna and ground terminals of the receiver to these two terminals on my bench. That will connect the receiver to my test antenna; just a random length of wire out to the old maple tree . . about 65 feet, and to my ground system . . the cold water piping of the house in this case. Now Judy, it's your receiver so the honor of ushering in the first signals should be yours. Again, follow the

100 73 MAGAZINE

Joe, Judy and Judy's Dad Tom finished the last steps in building the Coner receiver.

procedure outlined in the book, setting all of the controls to the specified positions. Now, slowly turn the main tuning knob slowly across the dial scale." Wow! From the myriad of peeps, whistles and birdies of every imaginable pitch which rattled the speaker, one would think that an emergency evacuation of a monstrous apiary was being staged!

Completely awed, Judy's jaw dropped, her eyes momentarily glazed and she slowly turned to FN with a blank and unbelieving stare. Laughingly he said the magic words, "Well girl, you've really made it; you grabbed the bear by the tail but you can relax and let go now. Let's see what we've got". Reaching across to the tuning knob, FN picked off a shrill high-pitched signal of more than adequate room volume and far above the speed capacity of the kids at this stage. Reducing the gain to a more comfortable hearing level he announced . . . "That's NSS at Annapolis, Maryland . . a Navy station. Here in Ohio we consider that as practically local; let's keep going. There . . another Navy . . NAA up in the state of Maine . . . we're doing better. Now, who's this? CKN . . . that's still better . . .

out on the West Coast in Vancouver, British Columbia . . . Canadian Government station. So, we're in the commercial and military portion of the 40 meter band . . let's see if we can chase down the amateur segment. Should be about here . . nope, that's a foreign short wave broadcasting station although the dial reads in the amateur spread. Could be though as many of those furriners show total disregard for international frequency assignments and just bust through wherever it suits them. Or, it could be that your dial pointer actually is off and the BC station is in a legal spot. Remember, we have made no effort to relate the pointer to the dial scale as yet; that's a minor adjustment and is explained clearly in the book. Before you tackle that let's see if we can grab a few ham signals somewhere on the dial to give us a cue which way to go. We'll tune slowly over the whole scale; commercial, commercial, Navy . . a voice but it sounds like a Mexican short wave BC station. Here's another voice . . wait . . that's in English . . put the BFO knob on AM and retune slightly; fine, and it's a ham calling "CQ 40"; listen. A WA6 . . . that's out in California . . Sacramento, he says. Well, we've hit the high end of the 40 meter ham band then; phones in that band are authorized to use the frequencies from 7200 to 7300 kg, or if you prefer, kHz, but your pointer is almost at the high end of the scale . . about 7600 kHz for a guess. Means vou're going to have to back the pointer up a bit and at the same time hold the position of the tuning capacitor plates. Suppose we pick the middle of the amateur 40 meter band for a starter . . 7150 kHz. Now there are two ways to make this adjustment and you're going to have to juggle a bit between them. The manual is very clear in explaining both the mechanical adjustment involved in shifting the pointer as well as the electrical setting to be achieved by adjusting the slug in the proper tuning inductance. I'm going to set my signal generator going at exactly 7150 kHz with the 400 hertz (cycle!) modulated tone turned on; there. Now tune in that signal; that's it . . that steady drone. Your job now is to keep that tone and adjust the pointer both mechanically and electrically until it indicates exactly 7150 on the scale. Go ahead now and follow the procedures described in the book."

Never a speedy process, this took a bit

of time and an occasional tip from FN but after some ten minutes of careful adjustments. Judy had it made and her beaming face reflected satisfaction. After an 'OK' from FN he continued, "Suppose, Judy, that you take a little breather now and we let Joe take a whirl at doing the same thing but on the 80 meter band. From here on the adjustments will be purely electrical so that we don't upset the mechanical position which Judy has established for the pointer. Joe, set your band switch on 80, put the BFO back on CW and follow the book." Again an encouraging number of signals though not so many as on 40; 80 meters in the daytime is not the best band in the world except for relatively local contacts but there are generally sufficient signals to permit the adjustment process. Hams, except for the novice sector and maybe a few phones are somewhat lacking but Joe had soon established a starting point and using the signal generator, this time set for 3725 kHz, took about the same length of time to corelate the pointer and dial with the tone and adjusting only the tuning slug in the proper coil. All that was now left was the 15 meter band and this being somewhat trickier in balancing due to the higher frequency. FN worked with both youngsters to bring this novice 'DX' band into proper play with the help of the scores of signals present as the band was 'open'.

It had been a rather rugged but very fruitful several hours and successful completion of the receiver was celebrated with a heaping mound of Grandma's famous doughnuts and a jug of fresh cider which FN produced from a dark corner cupboard in the cool basement. "What a day" . . . "Boy, that was rough" . . . "Whew; I think I know a *little* somethin' about a superhet receiver now" . . . and similar outbursts were bandied about. Soon the doughnuts were reduced to a plateful of crumbs, the cider level to a significantly new low and relaxation was complete. By now the afternoon was well along and as Joe had come out with Judy's family rather than on his Honda, Tom would take Joe home and stop in town on the way back to pick up 100 feet of antenna wire and a couple of insulators; he and Judy were determined to get up at least a temporary antenna of some kind as soon as they got home! Why waste Saturday evening on some dumb gunplay on the boob tube tonight?

All loaded, the receiver carefully held on Judy's lap (just try and take it from her!) the little band took off amid a chorus of " 'Bve Gramps and Gran . . . thanks for the help FN . . . sure had an enjoyable day". FN had instructed Judy in the adjustment of the antenna trimmer once she had the receiver connected to her own antenna and had reminded both kids that the following Saturday was their formal code exam day . . . don't get off the practice track meanwhile. They had earlier assured him that they had both sent their request for license application forms to FCC a week ago and hoped to have them to bring to the code exam.

It had been a somewhat wearing day and FN, though a bit on the weary side, had thoroughly enjoyed joining in the enthusiasm of youth but now sought a bit of peace and quiet through a little 'rag-chewing' with a few of his old cronies on the air until the welcome chow call ended the working day.

. . . W7OE

Next month: The formal code exam and a discussion of transmitters.

Dating Batteries

Too often it happens that when we use a piece of gear such as a portable transceiver, a transistor radio, or a flashlight, its batteries will pick that moment to take their departure to the Great Beyond. One good way to minimize these annoying occurrences is to write the date of purchase on each battery. With that date inscribed on the batteries, one can tell at a glance approximate-

ly when they should be replaced.

It is best to write the date on self-sticking unprinted labels or pieces of masking tape and then sticking them to the batteries. On batteries with cardboard cases, the date may be written in ink directly on their cases. A rubber stamp is also suitable for cardboard cases.

. . . William Bakewell WB6GHB

WTW Gets Under Way

You fellows who have been waiting to get into the WTW DX award should start right now because things have started rolling, interest is building up fast and the cards are starting to come in from all over the country. So far none have arrived from overseas stations, but you can be sure that many of them are working on it at this time. I had no idea that anyone would qualify during the first year (actually only eight months), but as usual I guessed wrong because many fellows have already sent in their cards and more are arriving as each week goes by. I wish I could enter this one but I have disqualified myself because I don't want anyone looking down their nose at me nor do I want any suspicion that there was any monkey business. Up to now I have personally checked each QSL card and they have all looked good so far, but we are putting everyone on notice that if the dates and call signs on each card are not easily readable they will be rejected. We don't want anyone getting peeved at us about such matters, but I want to put everyone on notice that we are going to be looking at every card sent to us with a strong reading glass and if any looks even the slightest bit "phoney" we will reject it without batting an eyelash. We suggest that you carefully look over your cards before submitting them and get duplicates of any that are a little fogged up, blurred, call sign changed, dated changed, etc. This will save us the trouble of rejecting the cards at this end and at the same time it will keep us from even the slightest suspicions of any of you. So far I am glad to say that all the cards submitted have looked ok, but sooner or later I am sure some questionable ones will show up.

When you fellows send in your cards for WTW how about sending along a few photos of yourself, your station, antennas, and some biographical dope so we can put it in 73 when writing up your reports. Presently quite a few fellows have qualified for WTW and as time goes on we expect the country totals to build up fast. Getting the cards has been a problem from some stations, but they can be extracted because I have seen all the cards submitted and this shows that it can be done. If you are being bothered by not receiving QSL cards, maybe you have worked the wrong stations! I would like to emphasize the importance of filling out your lists of QSL's that you send to me or any of the verification clubs. We would like for these lists to be done the same way by everyone who submits cards to us. Later on we will have some printed forms for everyone to use, but for the present time use standard 3 by 5 inch filing cards; we will let you know when the forms are available.

Put your call sign and address on each 3 by 5 card along with the date that you mailed the card. Please include your claimed contacts in the order of their prefixes (alphabetically), the date of the QSO, and the country you claim the QSO was with. I have received quite a few cards with no countries listed or dates. If this information is not shown on your filing cards in the future, the whole kit and kaboodle will be returned to you without any record being made that we have received them. This will place you further down the WTW list with a higher serial number on your WTW certificate. I'm sure you don't want this to happen.

We have issued nine more WTW certificates since the list we published last month. These fellows all got low serial numbers on their WTW certificates and one of these days they will be very proud to show these low serial numbers to the other fellows. Many more of you can do the same thing if you hurry and get your cards to me. Although I didn't mention it last month, note the Dan Redman K81KB and Jim Lawson WA2SFP each have two certificates: Dan has one for CW and one for SSB while Jim showed with 100 pasteboards for SSB on both 20 and 15 meters. These are no mean feats when you consider that it was all done in less than a year.

Bob Wagner W5KUC, "Hop" Hopple W3DJZ and Gay Milius W4NJF have gone one step further. These fellows have gone

all out on 14 MHz SSB by working and getting QSL's for 200 countries in less than one year. This just goes to show that it's not impossible if you work stations that QSL promptly. On the other hand maybe these fellows have some secrets about extracting cards from some of the toughies?

Are we going to count K1IMP/KC4's operation on Navassa? You can bet we will count it—they were there weren't they? In the future you can be sure that the WTW Awards Committee will count all such operations if the country is on the WTW countries list and the operator was actually there. Please pass this info on to any of your friends who are planning a DXpedition to some good spot. If the country is recognized by one of the national amateur radio societies, WTW will give credit and

their trip will be worthwhile.

Next month I hope to have a complete list of all DX Clubs which we have appointed for checking your WTW cards. This way your cards won't have to be sent so far; you'll save on postage and there will be less chance that your cards will get lost in the mail. We have quite a few check points already, but we are still looking for DX Clubs in the following areas: W1, W2, W5, W8, W9, WØ, Africa, the Middle East and South Asia (India, Pakistan, Iran, etc). Any volunteers?

We still have not heard from anyone for either CW or SSB on 10, 40, 80 or 160 meters, so certificate number one is still QRX for some sharp operator. Number one on 15 meter CW hasn't been claimed either. so fellows, join the WTW fun; come on in, the water's fine.

WANTED

SALES ENGINEERS EARN

\$20,000 per year

Based on commission from sales and installation of just 3 Vanguard TV cameras per week!

Full or Part Time

Closed circuit TV is recognized as a definite necessity for many businesses to combat rising costs. Thousands of factories, office buildings, banks and schools will welcome your demonstration.

Using our list of applications as a guide you will be able to show how any establishment can use several cameras and how each one can save thousands of dollars through the resulting increase in efficiency and security.

If you are over 21, have a working knowledge of TV and are financially responsible, we need you as a sales engineer to demonstrate our Model 501 in your area. To receive your application and additional details, send us a resume of yourself and include a self-addressed, stamped envelope.

Gus: Part 22

At the end of my last "chapter" I was with John, 9U5JH in Burundi. My stay with him and his small family was a FB one, plenty of good food, sleeping all day and operating all night. I wonder how it would have been if 15 and 10 meters had been open so I could also stay up all day to work the fellows? I suppose you could work yourself to death with all the bands open like they are right now. Maybe soon I will get to know if I get away on another trip. Don't be surprised if this happens. Right now my little weekly DXERS magazine is working me 14 to 16 hours EVERY DAY, but I am sure it will smooth out and I will be able to get away on another trip, sooner or later. During that time there will be a single page bulletin to keep all the DXERS informed.

After about five days of operating in Burundi I asked John about how things were up in Rwandi and was told that there was some "political" trouble up there. I later on found that there is "political trouble" most of the time in most of those countries down there. Sometimes it's bad and other times it's sort of mild. John said he would drive me up there the next day. We were up with the chickens and away we went on those rough dirt roads they have there. It's up one hill and down another all the time. Many natives was passed on the road. Where they all were going I had no idea. Some were loaded with quite large bundles on their backs. Many had very large stalks of bananas, I suppose carrying them to some market somewhere. Who bought them I don't know, because everyone there seemed to have lots of banana plants all around their houses (grass huts).

After about a 25 or 30 mile ride we

arrived at the border of Burundi and Rwandi. The Burundi guards just waved at us, but when we entered Rwandi about five guards stepped out with their rifles and pistols in the very middle of the road. They make us get out of John's Chevy and led us into the little Border Guard house where we had to answer endless questions as to why we were going into Rwandi and what our business was there. We kept insisting we were going there to visit a friend. They wanted to know who he was and what did we want to see him about. John said we were going to visit Father Florin 9U5BH, and that he was an old friend who we had not seen for a long time. I all of a sudden got a "brilliant" idea. Why not take some pictures of all these guards with me in their midst. We all trouped outside, lined up and took lots of pictures. I explained to them these were color pictures and would have to be sent to the USA to be developed. I think all this picture taking business sort of took their minds off all this questioning. All the radio gear was in those Samsonite suitcases in his car all this time, and I am sure if they had made us "open up" we would never have been allowed to enter Rwandi. It seemed there was two political factions in this country and it was nip and tuck with them. The border guards finally let us thru with us promising to send them some of the pictures when they were developed.

Which reminds me, I never did send those pictures to them. In fact I lost their names and addresses a long time ago. At least my intentions WAS GOOD AT THE TIME!

After passing into the country we started passing different group of people along the

road, dressed as if they were going to a party in their finery, and that "out of this world" hair-do they sport down there. Right down to the top of their head they had shaved a gap about one half to one inch wide and on each side they piled up their hair. Usually one side was a lot higher than the other and some of their hair-do's looked sort of like a hat at a distance. The people we met along the way started waving their hands at us I than noticed when they did this some of them would hold up one finger and others help up three fingers. I asked John what did this mean and found that this signified what party they were for. John suggested that we always wait and let them wave first and whatever fingers they held up that we do the same. John further explained that he had heard of some people in cars who made the wrong gesture and got a rock thru their windshields. Well being an old "hand shaker from way back" this was right up my alley. I became one of the boys from then on. Another few miles and we came upon a very large crowd of people out in a field by the road. A speaker was on a little platform, waving his hands all around and they had a VERY LOUD speaker system blasting away. Sort of "war looking" dances was taking place all over the place. I yelled to John, "stop the car". We stopped and I grabbed my camera to get some shots of all these shennigans, in fact I did actually get a few shots, and the crowd then saw us and we became the center of attraction and their looks was a long ways from being what you would call friendly. John said, "Gus, let's get away from here right now, I don't like the looks they are giving us." I agreed with him and he stepped on the gas and away we went like a scared jack rabbit. That was one place I were not overly anxious to hang around. Mind you this was in what I would call "wild country" of mid-Africa. Our intention was to go on to the capital city but when we stopped by to have a short visit with Father Florin and began to inquire about the possibilities of an operating permit and after Father Florin told us how unsettled things were up in the capital, and when he "invited" me to stay with him-I right then and there decided that half a loaf was better than no loaf at all, and I unpacked the gear. I was shown my own private room where all the other Fathers lived, and told the time to be at the eating table for all my meals. Father Florin and

ALLTRONICS-HOWARO MODEL L RITTY CONVERTER Telewriter Model "L" frequency shift converter designed for two-tone AM or FM with limiter operation available by switch. Solid state ratio corrector compensates for fading signals. Permits copying on Mark or Space only. Selector magnet de loop supply built-in with blas supply and octal socket for optional polar relay to key transmitter. 6W6 keyer tube. Plugin discriminator for 850 cycle or other shifts. Cathode ray or dual eye indicator. Auto-start control system optional. Prices for 19" rack mounting: Model "L" with dual eye \$199. Model "L" with C. R. tube indicator, \$279. Cabinet \$19.50. Radiation Loop for use with home radios, \$1.25

Order HERBERT SALCH & CU. From:

Marketing Division of Tompkins Radio Products Dept. 74, Woodsboro, Texas 78393

I headed for the radio shack some few hundreds of feet away with all my gear. I found that Father Florin's knowledge of English was extremely limited. His native tongue was Flemish. We could not do much talking but we most certainly tried, me in English and him in Flemist! That was some "eye ball" QSO, but you know amazingly we somehow did get thru to each other. I still wonder how we did it. I suppose if you wave your hands, yak and yak some more, roll your eyes, wiggle your ears, thump your nose enough you can finally get thru to anyone. Father Florin had quite a big batch of equipment there, all on 15 meter AM phone when I was there and he offered to let me use it. I explained to him that I would rather use my own. He had up a three element beam and nice "V" beam on the USA. We cleared a space on his desk and wired up my gear, Everything was checked out and away I went signing 9U5BH. All my followers were hand, quite a few saying I was a new one for them (which I still doubt!). After 20 went out I tuned up on 40 and it started all over again (I built up a little antenna tuner to use the "V" beam on my 52-ohm pi output gear). I even tried some 80 meters but did not have too much luck with it. The bands stayed open up till about 4:30 AM everynight. I had asked Father Florin about lions around there and he said there were a few now and again. This made my little walk from the radio shack to my room interesting each night at around 4:30 AM. I did actually hear some lions in the distance doing a little roaring, but am glad they were some distance away from where I was. I feel absolutely safe as long as they were some other place. During the daytime you are safe in lion country since they do their roaming around during the nightime. This place where Father Florin staved was a very large Catholic school with some 2.000 children going to school there, quite a number of them living in the school and the rest in the village. The ages were from 6 years to about 16. I wonder if Father Florin is still there, in fact I wonder if the school is even there with all the "changes" taking place in Africa these days. You know Burundi and Rwandi join the Congo, and Father Florin is from Belgium, and some of these Congolese don't exactly love Belgians. The Congo is very close to where Father Florin's school is located. All of the students there are natives, many different tribes being

represented by their different hair makeup, dress and many of them, they say, can hardly even speak to each other. Father Florin has a little "Broadcast Station" there which had a pi output network, which he had connected to the "V" beam, one side of the "V" being grounded. Naturally it would not load up, so I built a tuner for the "V" beam and we were in business with it. Everyone including Father Florin was delighted and so was I. He had a very large assortment of phonograph records and wanted to broadcast a few hours each day for listeners in the village and nearby.

My stay with all the Fathers there was most enjoyable. Radio conditions were very FB and when it came time for me to depart he insisted that I come back by there after I had visited other parts of Africa and spend three or four months with them. Over the air I even got someone to send him a modulation transformer for his "broadcast station". I hope it arrived OK after I left. It would be fine to visit him again and see how he is progressing with his BC station if he is still there.

John drove back from Burundi and picked me and my gear up and away we were off back to his QTH. We drove one night over to Usumburu and visited the head of their Posts and Telegraph asking for permission to use my own call sign instead of John's. We were given his permission to use the call of 9U5ZZ at the QTH of 9U5JH. I only stayed there upon my return for about three or four days using that call sign. One QSO I had from there I well remember. It was a SSB QSO with ZS6ANE in Johannesburg. He asked me if I would like to go down to Bouvet Island? Boy this was for me you can be sure! I was told that it would cost me though and this put a little freight into me and my close budget. I very "meekly" inquired "how much", and was informed that it would be \$3.00 per day to pay for my food while on the ship. I was also informed that the ship was going there by way of Tristan da Cunda and Gough Is. This development was something I most certainly had not even thought would turn up. ZS6ANE further told me he had inquired to LA5HE about him going to their authorities to try and get me a license to operate from Bouvet also saying he had already fixed things so that I could use the call sign of ZD9AM from Tristan de Cunha and Gough island. I was told to be sure and be in

Capetown on a certain day, a day that was not too far away. This cut my stay at Burundi. John told me he would drive me to Kigoma in Western Tanganyika, quite some distance from where we stayed in Burundi. With my itinerary all of a sudden tightening up with this deadline to meet the ship in Capetown all my stops between Burundi and there had to be cut to the minimum. The way transportation is in that part of the world you have to allow for delays (oh yes, you will have delays, this you can be sure of). Early the next morning (about 1AM) we were off. I had to get to Kigoma that afternoon or miss the twice-perweek train. Missing this train WOULD PUT ME LATE IN CAPETOWN, and THIS COULD NOT BE ALLOWED TO HAP-PEN, and worst of all MISS the trip to BOUVET ISLAND.

Next month: The trip to Capetown.

. . . Gus

Antenna Materials from Sears

If you browse through the Sears catalog, you find many items of interest to the antenna builder. The prices are very reasonable and delivery is as close as your mail box. For ground systems and ground leads, Sears has #8 aluminum ground wire at 50 feet for 95c; and to go with the wire, they offer % inch copper-clad steel ground rods 6 feet long for 89c. Compare those prices with your local hardware store! In addition, they stock steel antenna masts up to fifty feet, steel guy wire and lightning arresters.

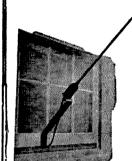

In the Sears Farm Catalog there are even more interesting offerings. For long wire antennas and extensive ground systems, you can buy a half mile spool (2640 feet) of #18 copper-covered steel wire for \$9.25; that figures out to about a third of a cent per foot. Be careful about using that #18 in a single strand long wire antenna, better twist two strands together. If you want aluminum wire, they have 14 mile spools of #13 for \$8.95. And-for tower installations, steel fench anchors are available. These little jewels are perfect for anchoring guy wires. Four sizes are available from a small 15 inch job that is rated at 450 pounds to a 48 inch unit that will withstand a ton and a guarter; reasonable too, check and see.

tion for amateur radio in Washington. And they should not suffer confusion over the role played by Bob Booth W3PS, the ARRL counsel in Washington, whose job is to present ARRL petitions to the FCC. Bob cannot, unfortunately, call up a Senator or a Representative and push ham radio for this is prohibited unless he is officially registered to lobby for us . . . and he isn't. Not that Bob could handle any such assignment anyway, for he has a full compliment of other clients and the ARRL is just one of many filling his time with their problems with the FCC.

The other major hobby groups have long since established headquarters in Washington and have strong and enthusiastic voices to protect their interests. I don't have to tell you about the tremendous results the American Rifle Association has had in convincing Congress of their members' points of view.

While there are many areas where the ARRL should be improved, I think that the most valuable long range results for all of us would be the long needed establishment of their Washington Office and the first real representation of amateur radio by the League.

I cannot answer all of the rationalizations that will be brought up against the above in this column. I can forsee a few . . . like maybe "it will be too expensive." Balderdash. Let's not hear cries of poverty while they have a half million or so sitting around in banks and stocks. That money should be out there working for us, not gambled on the market.

Pressure in Washington would not only work to the benefit of amateur radio here in our own country, it should also help to protect us internationally. The basic frequency bands are set by ITU agreement and if we are to hold onto our bands we must have all the support we can get in the ITU . . . and this means first and foremost complete and unequivocal support of our own government. In the last ITU conference in 1959 this was conspicuously absent and only a virtual miracle saved our bands from serious amputation. Are we going into future ITU conferences with the same lack of support? Unless we put pressure on in Washington it is going to be a repeat.

Not that the ARRL couldn't do a lot for

us internationally too. In my November editorial I explained about the need for gear in India, which has one of the best possibilities for expansion of ham radio in Asia, held back only by the almost complete lack of equipment. I sent copies of this editorial to the ARRL Directors and asked them to consider the proposal for collecting used ham gear in the U.S. and sending it to India, pointing out that I was well aware that a great many objections could be raised, and that I thought I had adequate answers for any objections or problems forseen. One director said he would do something about it if there was enough pressure from his constituency. One other said he thought the idea unworkable. Huntoon wrote and said that this was old hat . . . the League had considered a lot of stuff like that in the past and decided against it.

One of the biggest problems holding back the expansion of amateur radio in most of the Asian and African countries is the lack of equipment. We can get hold of a 50 kilowatt station easier here than some chaps over there can get a simple transceiver. We have tons upon tons of used gear sitting around in our garages, attics, cellars and in closets that could make a world of difference in a hundred countries. They don't care if it works or not . . . you get the gear to them and they'll get it working. When a transformer burns out in India they don't send for a new one, they take it apart and rewind it.

The ARRL could, if they wanted, spread amateur radio all over the world and spark the operation of thousands of new stations. In every one of the countries I recently visited that has a small ham population I found that there are many eager fellows who stay away from amateur radio because of the gear problem. The ARRL could easily collect equipment through the vast organization they already have set up and which reaches into every corner of our country.

The League history of helping overseas amateurs is a sad one of dropped balls. Their faint attempt in 1962 to work with Rotary International resulted in one single station being sent, I've heard, to a priest in Mexico. In 1963 the League tried to set something up with the Peace Corp, but this, too, came to naught after a couple of unproductive meetings. I gather that the Peace Corps wanted to set up a technical training program and the League held out for pro-

viding complete ham stations or nothing. And that's about it.

There is almost always a way to do something if you really want to do it. I found India most anxious to cooperate in the matter of receiving amateur radio gear and willing even to set aside customs regulations to get it. In other countries I found good possibilities of working through U.S. AID, a section of the State Department. Elsewhere I found the U.S. ambassadors quite interested in helping and there is a good possibility that gear could be furnished through our embassies. And so it goes . . . there are always problems, in anything . . . the successful executive is the one that solves them and achieves the ends in mind. Right now we need amateur radio in as many parts of the world as we can manage.

In addition to helping electronics and communications expand world-wide through our equipment help from the U.S. we will also be putting money in the bank toward foreign support in our frequency allocations of the future. I gather that the main hope at League HQ these days is that the ITU will be so politically strife torn that it will be unable to get together to take away our bands. This is, of course, a possibility . . . but should we bet our whole future on this chance?

By all this I don't mean to be disrespectful of the handbooks and code practice buzzers the League has sent to Liberia and Nigeria (donated by Johnson Company, bless them). This is good and no doubt has been responsible in some degree for the recent increase in amateurs in these countries. But what seems to be needed the most is gear and I don't think we will see any remarkable steps ahead until a program for sending equipment overseas is achieved.

DXCC Changes?

More and more of the DX clubs around the country are calling for an overhauling of the vague and conflicting rules of the DXCC award. The recent decision of the League not to accept the K1IMP/KC4 operation for credit toward DXCC seems to most observers to be nothing more than an attempt to get even with Don Miller for his upsetting of their Honor Roll apple cart.

Let me assure you that there will be no petty political maneuvering with the WTW award. If a station is in a country it counts for that country. There is no question what-

ever about Herb and Don actually being on Navassa, so the operation is valid for the Worked The World award.

Then there is the matter of a few DX stations that aren't just exactly where they say they are. The ARRL has set a policy of accepting these as counting for the country they claim to be in rather than the one they are actually in . . . and perhaps this is a good solution to the problem. I'd be interested in any good constructive ideas on this subject. I am uninterested in any emotional sanctimonious moralizing. This is something the League will have to eventually face too, for it is getting now to where an adverse decision on this could shuffle some honor rollers from ten to twenty countries.

A few days ago I got a call from K4ZBJ/MM. Seems that Jim is on a ship that spends a good deal of its time going back and forth between Fernando Po and Camaroon. Hmmm, says I, both of those are fairly rare, do you know that MM operation within the territorial limits of those countries counts as a contact with the country for the WTW award? Again, the thinking is that if the station is there, then it should count. This gets away from any political decisions as to who is legal, who isn't, etc. Look for Jim from those countries from now on . . . and any other MM's in unusual territorial waters.

The K1IMP/KC4 decision by the League is insupportable when you consider that they do accept contacts for DXCC with totally unlicensed stations in other countries. For instance, I am willing to gamble that they are accepting contacts with 9N1BG for credit. To my knowledge, and I was there not long ago, this station is unauthorized. This is not to say that there is anything wrong with the station or the operator . . . it happens that no public officials in Nepal have the slightest

Jim W5PYI (right) and I try noomie hamuph in Baghdad to fight off a chil).

intention of authorizing amateur radio . . . but have, on the quiet, encouraged amateurs to go ahead and operate, just don't ask for official permission. This same system is used in other countries and should be recognized as a fact of life.

W2NSD/YI

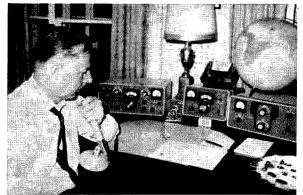

When I mentioned on the air that I was going to be stopping off in Iraq after leaving Syria and Lebanon a lot of fellows wanted to know if I would be getting on the air. I explained that if I could locate a rig in Baghdad I would, otherwise it was the tourist route for me. I did not take any ham gear with me on my trip, figuring that the problems of border crossing were bad enough as it was without being mistaken for a spy or something. I did manage to get on the air from most spots by visiting local ham stations. Nothing turned up in Baghdad, so I spent my time sightseeing.

Jim Cotten W5PYI and I arrived in Baghdad at night. We were a bit unsettled to have the customs officials pull about twenty boxes of cigars out of an arriving man's suitcase right beside us. The chap had forgotten to declare them. I suspect that he is sitting somewhere right now rueing this oversight.

We took a taxi into town with a chap that seemed to know his way around the place. Lucky we did . . . he bargained with the taxi driver for the fare and the trip cost about 50c. Later we found out that taxi fares are generally as high as the drivers can get. And if you make the mistake of taking a taxi on the promise of the driver that you can pay whatever you feel at the end you will have a real keepsake of Baghdad to remember . . .a royal gouging as he asks \$20 for the ride and holds out at \$10 for the police. etc. The gathering threatening crowds do not encourage you to hold out since he is screaming in their language and no one seems to know yours.

Baghdad is h o t. Our air conditioned room in the Baghdad Hotel was in the 80's and we slept fitfully. Outside it was in the high 90's at night and around 120° or so in the day. Try hiking around in that, fellow tourists.

Actually, other than the heat, we found Baghdad to be a nice place to visit. Unfortunately it was hard to think about anything other than the heat. Orange soda (Gus digs his Coke, I'm an orange fan . . . to each his own) was only about 4c a bottle so I survived

Hank Meyer EP3AM, the American Ambassador to

staggers through town by frequent orange soda stops. The native beverage didn't look all that good . . . large pans of watered yogurt with a block of ice in the middle. No doubt it is delicious. I may never know.

I did chance the ice cream being made by sidewalk venders though . . . great! And I kept up my sampling of various types of baklava (a pastry soaked in honey) at every opportunity.

The people were very nice to us and many asked if we would like to take their pictures. How different from Africa where the hands come out palms up as soon as a camera comes into sight. You take a picture of a street corner and several people come up menacingly asking for two shillings because you took their picture. Not so in Baghdad . . . they pose and are happy to be of service to you at no charge. I thanked several of them by presenting them with a Polaroid of themselves, but after a few of these the word spread and I found myself almost buried in small kids who wanted their picture taken.

Jim and I took a tour about 60 miles from Baghdad to Babylon and about got our brains fried inspecting the tower of Babel, the summer palace remnants, and other historical trivia.

We had been wondering about the big posters that had suddenly appeared around the city . . . the mobs in front of some government buildings . . . and other puzzlements. We got the word, at last. Seems we were in the middle of a cholera epidemic and didn't know it. All borders to the country had been sealed . . . fifty dead outside of Baghdad, about 15 in the city . . . etc. No one could enter or leave the country unless they had had cholera shots within the last three months . . . and this included just about everyone. Jim and I were about the only ex-

Remarkable turnout for hamfest in Tehran at EP2GF's shack.

ceptions, having had our shots just two months earlier, so they decided to let us out if the airlines would take us.

Much to our relief we arrived in Tehran the next afternoon via Iranian Airlines. The plane was hours late, but we didn't complain. They sent over a small plane since there was just the two of us for the flight. We breathed a sigh of relief to be away from the cholera epidemic and also to be out of that blast furnace type heat. Tehran was warm, but not unbearably hot.

As soon as I checked into a hotel I called Hank EP3AM, the U.S. Ambassador to Iran, to pay my respects. I'd last talked with him on twenty shortly before leaving New Hampshire. Hank was packing to leave for a vacation the next morning so we made a date to get together that evening for a short QSO. Gerry EP2GF picked me up and took me to see Hank. We had an hour and worked over most aspects of ham radio pretty thoroughly . . . got a couple twenty meter contacts . . . and discussed the future of amateur radio in the mid-east countries.

Gerry said that the EP gang was getting together a couple nights later at his place to meet me. Why not stay at his place instead of that old hotel? OK. Jim said he would rather buzz on ahead to Afghanistan and meet me there a couple days later since he wasn't one of the DX gang anyway.

Gerry lived with a couple other fellows who worked with him at the U.S. armed forces television station in Tehran. Quite a pad too, complete with a pool and cute little Persian girls tittering around. Also one ham station which I promptly put on the air and manned during every spare hour until my departure.

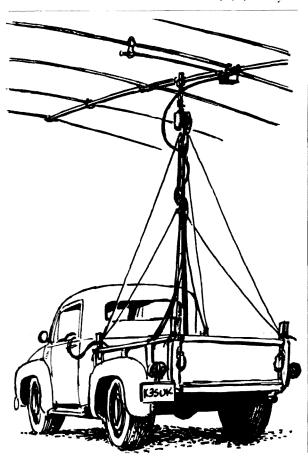

Licenses had been easy to get in Iran up until a few months ago when, suddenly, they stopped. No one knows just what the problem is or when or even if they will start issuing licenses again. There are a number of locals licensed, which speaks well for the country. Gear is hard to come by, but not impossible. Anyone seriously interested in operating can scrounge up enough to make do.

Although Damascus and Baghdad had some relatively modern parts of town, Tehran was a good deal more modern overall. Gerry took off a day and showed me the sights, including the bazaar, with its hundreds and hundreds of tiny shops strung out along tunnel-like streets. You wouldn't believe all the carpet stores they have there. And Gerry explained that these Persian carpets are more like money than carpets . . . that many of the modern people are buying American carpets when they want carpets.

About thirty of the local amateurs and their wives turned out for Gerry's party and we all had a great rag chew and feed. It was quite a hamfest.

The next morning I was on my way to Kabul and adventure in one of the most interesting countries I visited on my trip.

. . . Wayne

Letters

Dear 73:

First I would like to tell you that it has been several years since I have picked up a copy of 73. This happened because I more or less was interested in the hobby for a while. At that time I was subscribing to QST, CQ, 73, and VHF AMATEUR. I let all of them run out except QST.

About two months ago I picked up a copy of 73 a friend had down at work. After spending several days almost reading it cover to cover I ordered the following books: Military TV, Index to Surplus, ATV-Anthology, and Parametric Amplifiers. I must say I was very impressed with the quality and material of the

books.

For the past couple of weeks now my interest has been steadily building to the point where I have now checked out a 6 meter converter, purchased a used 2 meter converter and pre amp., dusted off the old BC-312, mounted the 6&2 meter beams, and will soon be trying the Heath Kit Seneca to see if it blows up when I turn it on. I also use to work on 432 MHz but that will have to wait for a little while.

I can honestly say that all of this interest has been sparked by reading a couple recent issues of 73. The many technical articles are related to up to date circuits and modern components. There are at least a half dozen circuits I have seen in the October and December

issues that I would like to build.

Now the reason I am writing this letter is that I have a rather unusual request. I would like to start another subscription to 73 with the October 1966 issue. This is the first issue that I looked at and there are a couple of the circuits in it that I would like to build. I am afraid that I could not get a single copy away from my friend for anything. Trying to find 73s in the second hand book stores around here is a lost cause also.

So if it is not too much trouble would you please start by subscription with the October 1966 issue. If this can not be done then do the next best thing and start with the latest issue.

> M. Robert Barnett WA2EWA Rochester, New York

Dear Mr. Green:

An agreement permitting U.S. amateur radio operators to operate in India was recently concluded with the Government of India. Under the procedures established, an American amateur who wishes to operate in India should apply to do so, preferably before leaving the U.S., by writing to the Wireless Adviser to the Government of India, Department of Communications, Sardar Patel Bhavan, Sardar Square, Parliament Street, New Delhi 1, India. The writer should receive full details by return mail. You might be interested to know that several Americans are already availing them-selves of this opportunity and have received licenses to operate amateur radio stations in India.

> Donald W. Born, Second Secretary U. S. Embassy New Delhi, India

Dear Sirs:

I would like to correspond with a amateur who would like to assist a veterinarian in assembling equipment to monitor the heartbeat of an animal. I want to put a mike jack into the side of a pocket-size two-way radio that can be attached to the harness on the animal, so I can monitor it from my car, which has a receiver in it. I also need a sensitive amplifier to pick up the same on animals inside by clinic. Since I know nothing about building such, I need the expert advice of a ham interested in the field of veterinary medicine. Would appreciate hearing from anyone.

> Dr. H. Grady, D.V.M 222 Fletcher Street Thomasville, Georgin

Dear 73:

Reference is made to Bob Renfro's, WA4NXC, very interesting article in the November issue on the Air Force Eastern Test Range.

Since mention was made to the range prime and sub contractors, PAA and RCA, respectively, let us not forget another range contractor who is instrumental in up-grading the capabilities of the Eastern Test Range.

Federal Electric Corporation (ITT) is presently installing a submarine cable system for the Air Force, between Cape Kennedy and the downrange islands. The new cable will provide up to 270 4kHz channels on which telementry and tracking data, and voice messages, will be sent to the Cape in "real time."

> John J. Boucher WA2LME Manager, Quality Control FEC/AFETR Cocoa Beach, Florida

Dear 73:

I have been involved in ham radio since 1956. under my old call of K9EBC and of late WA9TJT. Operating, exclusively, VHF-UHF because it presents more challenges than any other part of the spectrum.

Today, I have received by first subscription copy of 73. The contents, as compared to other

ham magazines, are commendable.

But, gentlemen, this is the beginning of our end. Technical advancements made today and tomorrow will further transport us from technical leaders to meek followers, beginning to learn.

It all started in the days when AM was in vogue. Hamdom decided it needed something bigger, better, and newer. HAIL, the birth of S.S.B. Industry has spent billions in research, redesign, and promotion for us, only to do it

ail over again for solid state.

We, of simple hamdon, wonder what is in store for us? 1966 has come, departed, and its memory is gone with the countless millions of ham dollars. Now we are blessed with Super-colinears, 2000 watt PEP linears, Solid state (\$1500.00) receivers, Single side band, Moonbounce, Scatter, Monolithic circuits, Maser, Laser, etc. In summation I have but three questions: 1) When will ham radio, as we know it today, perish? 2) If it does not perish, when and of what wealth will it he available. whom and of what wealth will it be available to? 3) What shall we write as an Epitaph?

> James A. Kohlman, WA9TJT Chicago, Illinois

Dear 73:

RADIO NEDERLAND, the Dutch World Broadcasting System, has asked me to notify the American Amateur Radio magazines, that they will conduct a Propagation Course in their English language broadcast, starting on the first Thursday in April, 1967.

Presently, the transmitters from which this course will be broadcast, can be heard throughout the entire USA, with excellent signal strength, daily between the hours of 0130 and 0220 GMT, on a frequency of 9.59 MHz. These transmitters ar located on the islands of Bonaire, in the Dutch Antilles, just north of Venezuela.

The course will deal with many problems related to shortwave propagation, among which are:

Ground and Sky Wave propagation
The various Ionospheric Layers
Single and Muti-hop trajectories
Signal strength in relation to radio noise
Influence of distance, season, and time of day

The Sunspot Cycle
Solar Flares and
Storms
Absorption

Fading

VHF Propagation

Printed text material and diagrams will be made available, free of charge, to anyone who plans to actively participate in the course. Full details of the wavelengths of the broadcasts and their times, will be sent to those who enroll in the course.

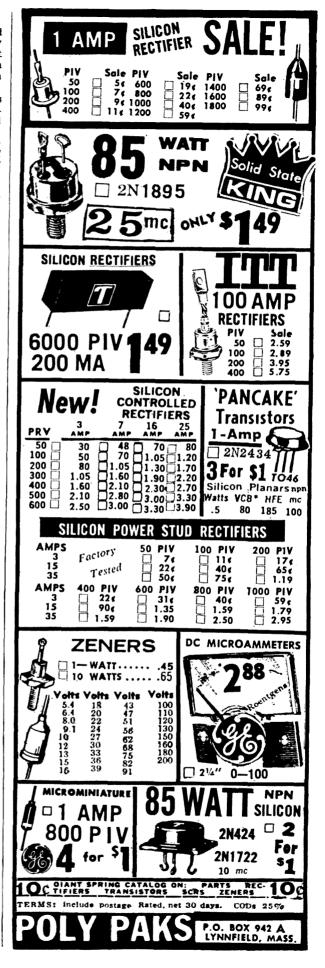

Enrollment is accomplished by writing to:

Propagation Course/ c/o Mr. H. van Gelder RADIO NEDERLAND, English Section P. O. Box 222 Hilversum, The Netherlands.

W1ICP Wins WWV Contest

WWV recently moved to Fort Collins, Colorado and sponsored a contest to publicize the move. The first person to report receiving WWV from Colorado was Lew McCoy W1ICP, Novice editor of QST. Lew called in his report within 30 seconds after the announcement of changeover. Second place went ot William Pearl, WN6UYW, of Los Angeles, and third to Willard Solfermoser, $K\phi$ DVI, of Fort Collins. Other persons who submitted confirmations will receive their QSL's in a few weeks.

New Products

49¢ FET's from Siliconix

Field effect transistors are getting cheaper and cheaper. Siliconix has just announced the E100 series of epoxy-encapsulated N-channel junction FET's for as little as 49c in 1000 quantities. They're excellent for industrial and consumer uses. Full information on the E100, E101, E102 and E103 is available from Siliconix distributors or Siliconix, 1140 West Evelyn Avenue, Sunnyvale, California 94086.

Times Coax Kit

VHF and UHF hams have known for some time that RG-8/U and other common coax is far too lossy for use in stations attempting DX or serious experimentation. However, solid-jacketed, low-loss coaxial cable has been hard to obtain in the past. Now Times Wire and Cable has introduced a kit of 50 feet of ½ inch Alumifoam coax, Timatch connectors, and complete instructions. This kit can easily be installed with no special tools, and provides far lower loss than other coax. You can get more information from Times Wire and Cable, 358 Hall Avenue, Wallingford, Conn.

Sydmur Electronic Ignition

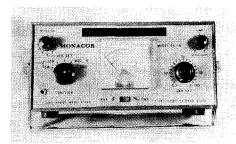

Sydmur has just announced a new transistorized capacitor discharge ignition system that is guaranteed to improve the performance of your car, and save gas, points, tune ups, and reduce ignition noise. It's made for 12 volt, negative ground systems, and sells for \$34.75 assembled, or \$24.95 in kit form, from Sydmur, Dept. 25H, Midwood Station, Brooklyn, N. Y. 11230.

Grundig Amateur Receiver

Here is a set that should make the XYL very happy: she can use it for FM, AM, SW or airport weather (LW), while the OM can use it for hamming: all-band band-spread. 160 through 10 meters, CW, AM and SSB, battery and AC operated. This is the most all-inclusive receiver we have ever seen, and no feature has been slighted, even a 1000 Hz filter. We kept a couple of SSB skeds with the TR5000 with no trouble, keeping the rf gain control at minimum. There is a connection for external antennas, tape and record input, and tape output jacks; two speakers, one a tweeter; treble and bass tone controls, FM with or without AFCthe reception was quite steady without it; built in whip antenna and ferrite loop (for AM band). The BFO, filter, AVC/MVC switches and the rf gain control are on the rear of the set, out of the way of family use of it so they won't be confused by too many knobs. The CW stability of this set is excellent-better than some ham sets we have heard, and this, of course, contributes to effective SSB reception. The tone of the audio is excellent, and is one of the reasons we think this will be a mighty popular family rig. This gem is being sold by Radio Products Sales, Inc. of 1501 South Hill Street, Los Angeles, California, 90015. . . . K1RA

17th Edition Radio Handbook

The 17th Edition of the popular Editors and Engineers Radio Handbook by Bill Orr, W6SAI, is now available. This new handbook is the latest version of one of the standards of ham radio, and contains not only the many pages of design information and reference material that all hams need, but also many new construction projects. All of the information is up to date and useful. The 17th Edition features expanded chapters on SSB gear and semiconductors. The cover is an attractive stain-resistant white, and the book is 832 pages long. Copies are available for \$12.95 from your local radio distributor or from Editors and Engineers, P.O. Box 68003, New Augusta, Indiana 46268.

The Monarch FSI-4 SWR Bridge, Modulation Meter, Power Meter and TVI Filter

This new instrument from Monarch Electronics should find a place in the shack of many hams, both old and new. Although limited to 250 watts or so, the FSI-4 is a compact unit that includes an SWR meter, modulation meter, power meter and TVI filter all in one neat package. The power limitation of 250 watts is due mainly to the components used in the TVI filter; with a cutoff frequency of 55 MHz, the components used in the filter limit the maximum power input to 250 watts up to 52 MHz. It is also usable on two meters with less than 1 dB loss, but the power input on this band must not exceed 50 watts. An additional feature of the FSI-4 is the built-in on the air indicator; this circuit is driven by an external 6.3 volt source so no power is derived from the transmitter. If you're interested in a unit that is good looking and provides several varied but important functions in the same package, write to the people at Monarch; they'll be happy to provide full specifications and tell you where you can buy it.

Knight KG-2100 Scope

Designed to appeal to a wide market, from the affluent big company R & D lab to the independent engineer with a limited budget, the Knight-Kit KG-2100 laboratory oscilloscope is a dc to 5-MHz triggered sweep unit with professional performance specifications. Among the special features of the 1967 model are lock-in characteristics that permit viewing stable waveform presentations even at upper frequency limits; a built-in Rotron fan for cool operation; high vertical sensitivity, 5 mv/cm, for proper servicing of transistorized equipment; 85 nanoseconds rise time; horizontal response from dc to 800 kHz triggered sweep-200 nsec/cm down to 1 sec.; regulated high and low-voltage power supplies. The dc to 5 MHz vertical amplifier response of the instrument permits the display of pulses of fast rise time. Both trigger and amplifier circuits are dc coupled throughout for uses where very low frequencies or dc levels must be displayed. Vertical off-scale indicators provide maximum convenience in viewing traces. Horizontal positioning is such that pattern is never completely off-scale left or right-even with external signals. Preset lock-in eliminates the need to synchronize sweep with inputs. Signals of various amplitudes and frequencies as small as ½ cm on the CRT face will permit triggering. Sweep range adjustable from 200 ns/cm down to .1 s/cm. Sweep timing accuracy capability within 3%. Adjustments for intensity, focus, astigmatism, positioning and graticule illumination. Color-correlated controls grouped by function for fast, accurate use. The KG-2100 oscilloscope is priced at \$249.95 in kit form, \$349.95 factory assembled. Full details available from Allied Radio Corporation, 100 N. Western, Chicago, Illinois 60680.

ALL OF OUR TRANSISTORS AND RECTIFIERS ARE GUARANTEED TO WORK! All transistors are checked for minimum voltage and gain to insure our customers a good transistor within the category we advertise. All rectifiers costing over 10¢ are checked for forward voltage and leakage as well as PRV. The gates on our SCR's are also checked. All non-operable units will be refunded or exchanged immediately. Users of the above items in larger quantities, send us your specifications. We feel we can meet them at a competitive price. Alco Isolation Relay

An interesting new device from Alco is an isolation relay, a combination 110 volt ac transformer and relay on a common core. It is controlled by low voltage, safe ac, yet can handle 5 amps at 110 V. Among the uses for the relay given in the instruction booklet that comes with it for \$3.85 are various remote controls, soldering iron tip saver, fire alarms, rain and burglar alarms, PTT switches, and many more. The View from Here . . .

As the new editor of 73, I would like to tell you a little about myself. Although I've been an avid amateur since my high school days, it took an army radio school to get me across the CW hurdle to my license. Since that first license in Virginia as K4RPW, I have operated from many places, both in this country and abroad. My latest call is W1DTY, a re-tread that hasn't been seen logged since before the big war.

My electronics background in the military took me into the computer industry, but the abundance of mechanical doodads took me too far away from electronics. A stint as a technician in aerospace cured that and gave me a chance to work intimately with the newest in electronics. However, electronics again fell by the wayside when I was promoted to a papershuffling desk job.

To keep my fingers in electronics, and particularly radio communications, I began writing for 73 and teaching electronics part-time in a junior college. Finally, I wrote to Wayne about employment at 73 — I was rewarded with the opportunity to work with the staff here in Peterborough.

My ham interests are varied. There just isn't enough time to do everything I'd like to do. I like to design and build my own equipment, experiment with new VHF and UHF gadgets, work contests, and just operate in general. Right now my big kick is chasing DX on all bands from 80 through 10. Give me a shout if you hear me on, I'll be glad to chew the fat or give you a New Hampshire contact for WAS. You VHF addicts will have to wait. I put up a beam for six but a windstrom promptly removed a couple of elements, and the New Hampshire snow is not conducive to tower climbing.

In my opinion, and yours too I hope, 73 is the best ham magazine on the market. We have less trivia and more good solid technical and construction articles every month than Brands X and Y put together. If you look back through the more than 2000 arti-

cles that we have printed in the past six and a half years, you will find articles on every facet of ham radio.

I will strive to have an article of interest to each of you in every issue. Don't be miffed if we miss you one month, there aren't that many articles written on some topics.

The biggest complaint that I hear centers around late delivery. This has been a continuing problem and we hope to have it licked in a few months. Our present schedule calls for a magazine every three weeks until we get back in the groove. This is a pretty tall order for our skeleton crew, so if we only put out an issue every three and a half weeks, please bear with us—that's still progress!

In the coming months we will have articles on field effect transistors, integrated circuits, and microwaves plus features on antennas, VHF and mobile. If there is sufficient interest, we may even have an article or two on electronic bugging. If you don't see your pet project covered, let me know—better yet, submit an article. A lot of ham authors started by writing for 73. I'll give you all the help I can.

If you get up to New England on your vacation this year, make a point of putting Peterborough on your route. Although you're apt to find the office deserted on the weekends, there's someone here from Monday through Friday. We're not hard to find either, just look for the towers. The very least we'll do is give you a guided tour, introduce you to the staff and try to sell you a life subscription.

If you can't make it to Peterborough, look for me at the conventions and hamfests. Time doesn't allow me to make all of them, but I'll try to get to as many as I can. If you don't find me wandering among the exhibitor's booths or at one of the technical sessions, try the snack bar. I've been known to buy a round of coffee.

Jim, W1DTY

ROHN.

Asks...How do you rate a tower when the stories all sound the same?

There is a one-word answer — PERFORMANCE!

ROHN TOWER performance has made it the top name in the industry. Wherever you go — worldwide — you find ROHN TOWERS — CATV, microwave, communications, broadcast, home TV and amateur — with complete accessories, lighting, microwave reflectors and equipment. ROHN TOWERS — the accepted standard — recognized as the towers that provide strength, durability, ruggedness, appearance, design, adaptability and prestige. ROHN popularity rests on these factors:

• Computer Analysis & Engineering Design • Manufacturing • Warehousing • Turnkey Tower Erection • Complete Lines of Accessories

Representation and Distribution Worldwide

de W2NSD|1 Never Say Die

Wanted: Involvement.

Thousands of amateurs govern their work and their very lives by the movements of DXpeditions. When Gus was scheduled to be on from some rare spot thousands of desks were empty until the contact was made. The DXers are keen and dedicated. You really couldn't ask for more in involvement.

Other thousands of amateurs and equally involved in traffic handling and the traffic nets. Others are hung up on ham-RTTY or ham-TV. Others devote years to a moment or so on moonbounce. Tremendous dedication . . . involvement.

This is good, I think.

One whole big segment of the ham population is almost impossible to lure outside the workshop. They're building things. They don't want to operate . . . to send messages . . . a lot of the time they don't even want to go to dinner or bed. Involvement.

Great!

A few fellows are all whipped up in the politics of ham radio. Some run for ARRL offices and are deeply involved in the League and its workings. Others are generating tremendous quantities of sweat over the Certificate Hunter's Club, the Amateur Radio Editor's Association, and the like.

But ham radio is not DXing, or traffic handling, or the ARRL, QSL'ing, AREA, or building gear. Ham radio is all of these put together, plus all other facets of our hobby. It is the total. And here is where we most desperately need involvement. Each aspect of our hobby has plenty of support, but the lack of fellows interested in the future of the total may be our undoing.

Is there anything that can be done about this? Ham radio is in reality not one hobby, but a whole group of hobbies and it takes an unreconstructed idealist to fight for something that he personally isn't particularly interested in. You don't see many DXers in there battling for reason on the splitting of the two meter band. The traffic men couldn't care less about what is or is not a new country. And so it goes . . . with the result that there is, essentially, no individual ama-

(Turn to page 111)

The Quad-Quad-Quad

Sixteen three-element quads for two or sixteen nine-element quads for 432 provide a very impressive antenna and signal.

What in devil is a quad-quad-quad? For that matter, what is a quad?

There are two common uses for the word "quad" as applied to antennas. When we put up four antennas in a square formation, we say that we have a quad of antennas. We may have, for example, a quad of 10 element yagis, for a total of 40 elements. The other use of the word applies to quad elements. A quad element is a square of wire, or tubing, which usually has a perimeter of 1 wavelength.

If you make four yagis with quad elements and mount them in a square formation, you have a quad of quads, or a quadquad. Doug DeMaw described such an antenna in the May 1964 issue of 73. If you put up four quad-quads in a box formation, you have a quad of quad-quads, or a quad-quad-quad. Such a monster is the subject of this article.

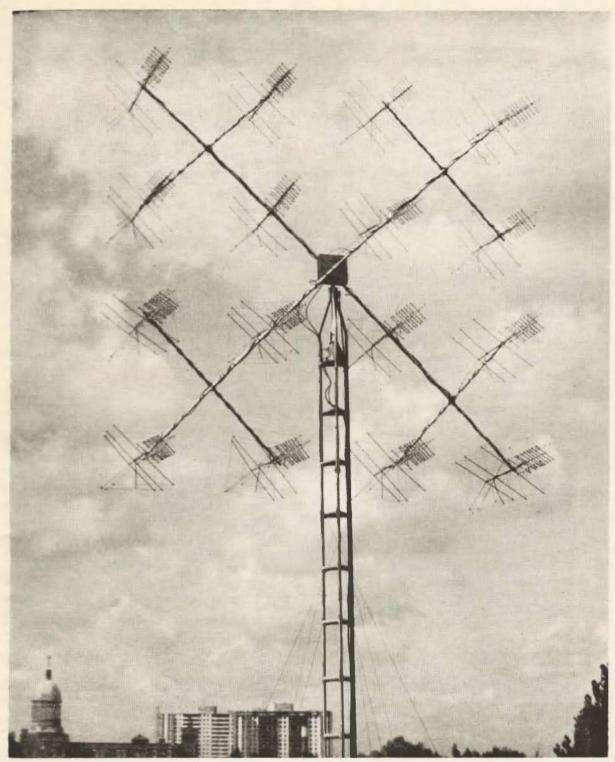

In the summer of 1964, I had the booms drilled and the elements cut for four 8-element yagis. Just before buying the tubing to mount the yagis, I overheard Russ, K2KGN, extolling the virtues of his quadquad, on 2 M. A bit of calculation revealed that it would cost less to start again from scratch and build a quad-quad, than to finish the yagis. The fact that no one else had a quad-quad in Metropolitan Toronto

settled the matter. You can't do better than your buddies if you do what they are doing.

In making the quad-quad, my first mistake was the use of aluminum clothesline wire. It sure is nasty stuff to solder. My second mistake was the use of open wire feeders. Open wire is nice if you can keep the wires parallel and you live where there is no rain or snow.

In spite of its deficiencies, the antenna performed fairly well, when the feeders were not shorted.

The advantages of the antenna are low cost and small size for the gain achieved. The elements have gain over straight dipoles, because they are really two half waves spaced a quarter wave apart. This allows you to use shorter booms for a given gain. With three elements, the boom is so short that you can support the boom behind the reflector. This keeps the supporting structure out of the antenna's field, which is always good. It also allows you to mount half of the array below the top of the tower. since the tower will be behind the reflectors. With the center of the array right at the top of the tower, there is no need for a long strong mast to carry the whole weight of the array in a strong wind. Only 2 inches of my mast is between the tower and the bottom of the mounting plates at the center of the array.

The quad-quad-quad array at VE3DNR. This antenna has sixteen three-element quads on two meters and sixteen nine-element quads on 432 MHz.

Designing the beast

After I had the quad-quad up, Russ, K2KGN, put another bug in my brain. How

about 16 quads? At first it seemed almost impossible for me. After months of thought, during the winter of 1964-1965, the difficulties disappeared one by one. Measure-

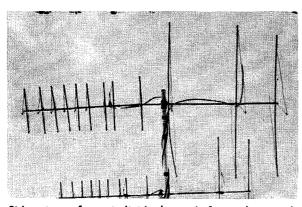

ments and construction were done during the summers of 1965 and 1966.

When you start thinking about a quadquad-quad, you soon realize that the spacing between yagis will be small, or the beast will be awfully big. A little more thought, with much calculation, reveals that this beast could also be awfully heavy. One of my early designs had a calculated weight of 120 pounds.

You must fight excessive weight as you would when building an aircraft. You would be surprised at the weight of such things as coax. The final design has a calculated weight of 54.4 pounds, including the mast and mounting plates. It is so light that I can lift it by the mast and remove the rotor, which is mounted inside the tower. The mast rotates in a collar at the top of the tower, so it is not necessary to hold it from going sideways.

I wanted to avoid mounting the booms cantilever style, but I still wanted to have the supports behind the reflectors. The solution was to extend the boom on the back side of the supporting tubing, and to put some sort of counter weight on that end. A nine-element quad for 432 MHz has the same weight as a three element quad for 144 MHz. So it was decided to put a 144 quad on one end of each boom and a 432 quad on the other end. The result would be sixteen 3-element quads for 144 and sixteen 9-element quads for 432.

The result had to be as small as possible, so it was necessary to redesign the quads to reduce the size. On the 144 quads, I found that I could bring the reflectors within 14" of the driven element without chang-

Side view of an individual quad from the quadquad-quad array. The nine-element 432 quad is on the left; the three element 2 meter quad on the right.

ing the gain appreciably. The reflector length was tuned for the minimum received signal off the back. The director was not at all critical. As near as I could measure it, the gain of one quad was 8 to 10 dB over a dipole. The front-to-back ratio was about 14 dB and there is a null off the side, as is usual with quad elements.

The design was actually done at 145 MHz, to cover 144 MHz to 145.5 MHz. Antennas usually cover more megahertz below the design frequency than above. When I refer to the 144 quads, I mean the ones designed for the 2 M band, not just 144 MHz.

With the 432 quad directors, I used the idea of a slow wave structure consisting of five equal elements with matching elements at each end. This was described by Loren, K7AAD, in the May 1965 issue of the VHFER. The 432 quads had measured gains of 14 to 15.5 dB.

Measurement

The measurements on the individual quads were performed indoors. Many will look with disdain on such an idea. The main dangers would seem to be the reflections from the surroundings and the effect of the surroundings on the impedance. It was necessary for me to put my hands very near to the quads in order to change their gain. I also observed deep nulls, which would tend to indicate that the reflections were not very serious. The room was not typical. It was a second floor, unfurnished, room with non-metalic insulation.

One advantage of the quad is that it is only a quarter wave wide. Therefore, it does not come as close to obstructions as would an antenna with ordinary dipoles. This would make indoor measurements more feasible with the quad than with the yagi with straight elements.

Measurements were made using the quad as a receiving antenna. A signal generator was connected to a dipole and a superregenerative receiver was connected to the quad, through 100 feet of RG-58/U cable. There was about 15 feet between the two antennas.

The idea of using a super-regen was to get a sensitive indication of when there was a change in signal. With a large signal present, the super-regen is very insensitive to changes in signal levels. On the other

hand, at the receiver's threshold, very small changes in signal can be detected. So the attenuator on the signal generator was varied so that the signal could barely be detected in the receiver. This gave a sensitive indication of when the quad was made better or worse.

The idea of using cheap and dirty RG-58/U for measurements also comes from Loren, K7AAD, in the May 1965 issue of the VHFER. Tuning an antenna for the best SWR does only part of the job. A dummy load gives a fine SWR, but it makes a lousy antenna. What we want is the maximum signal in a 50 ohm load attached to the antenna, in the receiving case. A lossy piece of coax gives its characteristic impedance at one end, no matter what is at the other end. So 100 feet of RG-58/U at 145 MHz will show approximately 50 ohms to our quad, no matter how lousy the receiver's input impedance is.

When we have adjusted our antenna for the maximum received energy, there is no more that we can do. SWR or no SWR, our antenna is putting out as much signal into a 50 ohm load as it can. So, I don't know what the SWR of this antenna is, and I don't care. I have done the best I can.

Characteristics Of quads

There are several features of the quad which should be noted. The square quad, with sides at the top and bottom, works better than the diamond quad, with corners at the top and bottom. The difference is not large, but it is measurable.

As shown on Fig. 1, a current maximum will be wherever you feed the quad. Since the quad is 1 wavelength around, the opposite side will have the other current maximum. This puts the current minima, and the voltage maxima, half-way between. With a square quad, the voltage maxima are in the centers of the vertical sides. With the diamond, the voltage maxima are at the side corners. Since it is convenient to have the spreaders supporting the corners, the diamond has supports at its voltage maxima. Unless these supports are high quality insulators, and therefore expensive, you lose quite a bit of power in the supports. The square quad has its supports away from the voltage maxima, and is therefore more efficient.

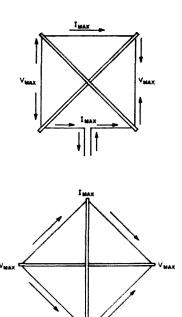

Fig. 1. The current and voltage maximums in square and diamond quads. The square quad is slightly more efficient that the diamond version because the supports are away from the voltage maximums.

For reasons which are a mystery to me, it seems better to solder the directors and reflectors at the current maxima. The opposite seems more logical to me, but my measurements clearly indicated this fact. Horizontally polarized quads should have their directors and reflectors soldered at the top or bottom.

The quad seems to be fairly sensitive to polarization. Rotating the quad on the axis of its boom by 90° produces a large change in the signal received. This is reasonable because the vertical sides of a quad, fed at the top or bottom, have currents flowing in both directions. This would cancel the vertically polarized signal.

The quad seems to be quite happy with unbalanced feeders. Measurements were made with a 432 quad fed with 50 ohm coax straight and with a 1/1 balun. The difference could not be measured. I was quite happy to save the weight of the baluns.

I can guess at the reason. With an ordinary dipole, the side connected to the braid of the coax is connected only to ground. It may get some signal from the other half, but it is operating at a disadvantage. With a quad, all of the element is connected to

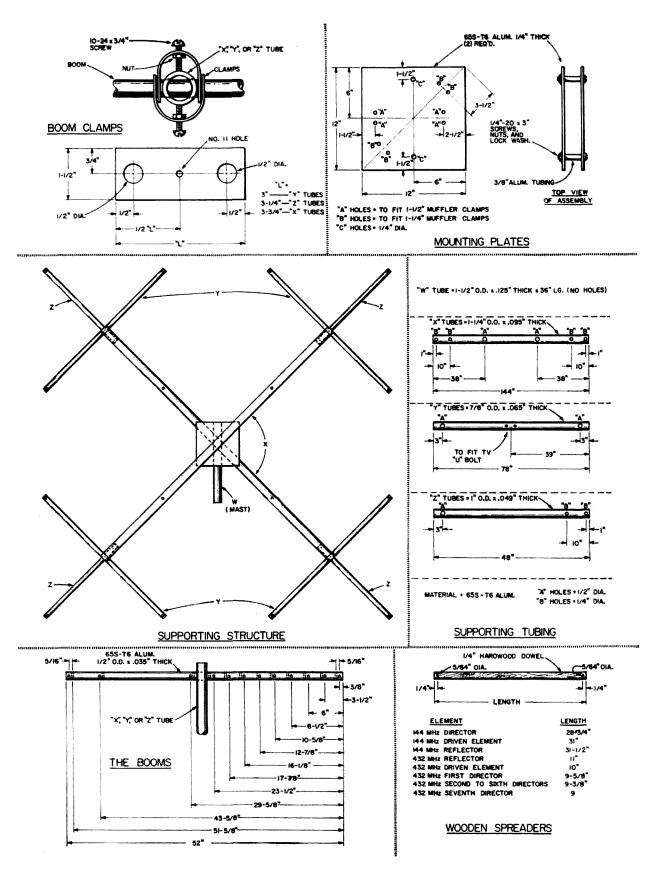

Fig. 2. Constructional details of the quad-quad-quad. The type of construction shown here results in a very strong unit that only weighs about 55 pounds.

the inner conductor, since the element is one piece of wire. It would seem that the quad element would be happier operating as an unbalanced antenna than would an ordinary dipole.

I see no reason to believe that there will be less fading with a large antenna. Although it is true that a signal will be received even if one quad is receiving nothing, it is also true that all the quads could be receiving something, but they could cancel each other. To me, one QSB situation seems as likely as the other.

If you want diversity reception, you must feed the signals from more than one antenna to more than one receiver, and add the audio signals. Only at audio frequencies can you keep the signals from the various antennas in phase. The 16 quads would seem to be good for a four channel diversity system. You could have the four quad-quads polarized horizontally, vertically and at the two 45° angles.

Construction

To save weight, the elements were made of #14 wire instead of the #10 used by Doug DeMaw. This may account for his superior front-to-back ratio. #10 wire for only the reflectors, which seem to be the most critical elements, may be a good idea. The spreaders were made of ¼" dowel instead of ¾".

The position of the holes in the booms are specified by Fig 2. The booms were drilled with %" holes so that the spreaders could be passed through the booms. This saves the weight of the circular hubs that Doug used. The booms are very thin. There is danger that you will bend the booms where the holes are drilled. I bent one while installing the antenna. Since an individual quad is light, it can't do much damage if it falls. Therefore, we can take the chance that we have made the booms too thin.

It looks much better if you can make the holes in the boom line up; it looks less of a mess to the neighbors if the elements are in a line. A drill press is handy, but you can do a fair job with an ordinary electric drill. I doubt that perfect alignment will improve the electrical properties of the antenna.

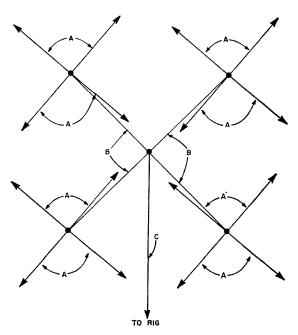

The size of the elements have been given by specifying the lengths of the spreaders in Fig. 2. If the wire is under a bit of tension,

you will come very close to getting the right perimeter every time. Even if the wire does not form a perfect square, the perimeter comes out roughly the same if the spreaders are the right lenght. The dimensions are not very critical. If you try to make the distance between the holes on the spreaders accurate, you should have more than enough accuracy.

Before putting the spreaders through the boom, you will find that you must file the holes in the booms. If you file the hole only enough to get the spreader in, you will need no adhesive to keep the spreader centered in the hole. It is easier on the nerves if the spreader stays put while you are trying to put the wire in place.

The booms are put through ½" holes in the supporting tubing. Therefore, you can only wire the quad on one end of the boom before putting the boom in the ½" hole. Since the 432-MHz quads have three times as many elements as the 144-MHz quads, you will naturally make the 432 quads first. You want to string as many elements as possible before getting the booms involved with the supporting tubing.

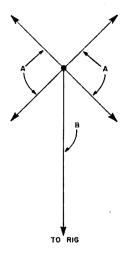

The ends of the spreaders were painted

with General Cement's Liquid Tape to cover the holes where the wire goes through. Then the whole spreader was painted with marine spar varnish.

The means of holding the booms in the ½" holes is one of the standard methods. The clamps are described by Fig. 2. Probably only one clamp per boom is necessary, but they are light and one clamp seemed marginal to me. Of course, you could weld the booms in place, if you know that you will never want to take it apart. Surely you will want to build something bigger in future.

The supporting structure was put in the form of a X frame. (Fig. 2) instead of the more usual H frame. This arrangement was used because it seemed lighter for a given strength. My only regret is that it would have been easier to tilt the H frame for moonbounce. Since I don't have the equipment for moonbounce activities, this doesn't bother me much.

The mounting plates (Fig. 2) are clamped to opposite sides of the mast (W) with 1½" muffler clamps. The 1¾" tubes (X) are clamped to the plates with 1¾" muffler clamps. To add strength to the assembly, ¾" aluminum tubes are wedged between the two plates, as shown in Fig. 2. These tubes are held in place by ¾" screws which go through both plates and the ¾" tubes. With this arrangement, each plate helps to

keep the other plate from rotating around the mast in a wind. I can't tell you what holes to drill for the muffler clamps because your clamps will probably be different from mine.

The Z tubes fit inside the X tubes and 2" from the ends of the X tubes, using TV "U" bolts. Since you probably will use different "U" bolts from mine, I can't tell you what holes to drill in the Y tubes. The Y tubes are bolted to the same side of the X tube as its mounting plate. This makes it easier to line up the quads.

The Z tubes fit inside the Xtubes and are fastened with \(\frac{1}{2}\)—20 screws, 1\(\frac{1}{2}\)" long. The holes in all the supporting tubes are specified by Fig. 2.

Since the X tubes are separated by the plates and the mast, we must compensate for the space between them. All of the quads must line up as close as possible so that they are all the same distance from the other fellow's station. Otherwise, the signals from the 16 quads will not add in phase. This is, of course, more critical at 432 MHz than at 144 MHz.

The booms in the X and Z tubes are pushed toward the center of the array as much as possible. By the center of the array. I mean a line drawn parallel to the X tubes which passes through the mast. The booms in the Y tubes are pushed (in my case) 3" away from the centers of the booms in the direction of the center of the array. The exact distance depends on the dimensions of your muffler clamps. This should make the quads line up to within ½" or so. You must also be careful that the Y tubes are clamped to the X tubes properly to make the quads line up. Finally, when clamping the X tubes to the plates you must rotate the X tubes so that the quads line up.

All of the muffler clamps and "U" bolts must be protected to prevent rust. I used Vaseline, because it is readily available and it has always done the job for me.

The cable harness

The coax connecting the quads together is small, RG-58/U size, cable. Naturally, the larger, RG-8/U size, cable would have lower losses, but more weight. Since the length of the cable from the common junction to any quad is short, the losses in small cable should be small. The additional

weight of large cable seemed intolerable. Below the common junction, the weight of the cable is supported by the tower and we can therefore use large cable for the

long run to the rig.

Fig. 3 shows the cable lengths for 16 quads. Each quad is designed to have an impedance of 50 ohms. So when four guads are connected together by 50 ohm cable, we have 50/4 ohms as the total impedance at these junctions. Each of these four junctions is connected to the common junction by 50 ohm cable which is an odd number of quarter waves long. These quarter wave sections transform the 50/4 ohms to 4×50 ohms. The main junction sees four 4 x 50 ohm impedances connected in parallel to give 50 ohms. The main cable to the rig is 50 ohms, so it is matched.

The cable used was made by Times Wire & Cable and distributed by Mosley. Any other cable could, naturally, be used if the velocity of propagation is taken into account. The dimensions in inches on Fig. 3 are for the Times cable. The distance in wavelengths required is, naturally, the same

for all types of cables.

For a four quad array, 100 ohm cable could be used, as in Fig. 4. An odd number of quarter waves would transform the 50 ohms of each quad (100/2) to 2 x 100 ohms. Four cables connected together would give \(\frac{1}{4} \) of 2 x 100 ohms or 50 ohms, to match the cable to the rig. The most appropriate cable I can find in the catalogues for the quarter wave sections is RG-62A/U; its impedance is 93 ohms instead of 100 ohms.

You may raise your eyebrows at the idea of connecting the cables without coax connectors. If you count the number of connectors that would be needed for the 16 quads on two bands, you can see the point of avoiding connectors. The weight, let alone the cost, of all those connectors is prohibitive. Therefore, we must do our best at making reasonable coaxial connections with

trusty soldering iron.

The five cables for each connection were laid out like five spokes of a wheel, as shown by Fig. 5. The inner conductors were soldered and the joint was insulated with tape. The outer braids were then folded over the tape to cover each side of the joint. The braids were then soldered together to form a solid shield all around the connection. The joint is fairly strong

(A) SOLDER THE INNER CONDUCTORS AND TAPE CONNECTION

(B) FOLD THE BRAID OVER, SOLDER, AND TAPE AGAIN

Fig. 5. Connecting the coaxial cables together without using connectors. The coaxial connectors required for the quad-quad are very expensive and add a lot of weight at the top of the tower.

after the braids are soldered. The finished connection is then taped and coated with some weather-proof material. I wouldn't recommend the coating that I used, so there is not much point in naming it.

Of course, you must be careful to connect all the quads in phase. All of the inner conductors must go to one side of the quads (eg. the right sides) and the braids to the other sides (eg. the left sides). If you goof on ½ of the quads, you will have a nice null where the main lobe of the pattern should be. These connections should be coated with something weather-proof.

The cables run up from the driven elements to the booms, along the booms and then along the supporting tubes. The cable is wound around the tubes and taped. The lengths of cable specified include enough slack to route the cable in the same way.

Getting it up

To show that it is possible, I decided to put up the beast alone. Unfortunately, my refusals of offers of help may have rubbed a few relatives, hams and neighbors the wrong way. It seemed important to show

that anyone out in the sticks could do the job without help.

The key to success is to have a gin pole, which is a piece of pipe with a pulley on one end. You bolt the pole to whatever is already in the air, with the pulley at the top. Then you pull up whatever is next with a rope running over the pulley. My pole is 12 feet of 1¼" aluminum tubing, with a clothesline divider bolted to one end with a "U" bolt.

The antenna was put up in three sections. The mast and plates were put up first. Then each X tube was put up with all the stuff that each one supports. The two main junctions of the coax (one for each band) were soldered with the antenna in place.

It isn't really easy to do the job yourself, but it is possible.

Performance

The antenna moves in two major directions in a breeze. As you would expect, there is a strong tendency to rotate about the axis of the mast. Since the rotor is of the TV type, it is not strong enough to keep this rotation under control. There is a clamp at the top of the tower, which allows me to lock the mast to the tower. This clamp can be controlled from the ground using a "rope and pulley" system. The system works, but I hope to replace it with some electro-mechanical system that can be controlled from inside the shack. A heavy duty rotor would cost 4% times as much and it still would not hold the antenna as well as my clamp. I have seen the way that some expensive rotors hold big ham antennas in Toronto and they impress me very unfavorably.

The other motion is rotation around the axis of the 1½" tubing. This motion is not too severe because it is limited by how far the X tubes will twist. This motion shows that tube Y must be clamped firmly to tube X. Plenty of wind force is available to twist tube Y around the axis of the X tube. Perhaps, in my next model, I will put braces between the X tubes and the Y tubes.

The electrical performance is difficult to state definitely. This antenna is the first one at this QTH which was made at all properly. There is no well made antenna at the same height that I can use for comparison.

Comparing my results with others is also not valid. My QTH is not at all average. The 60-foot tower for the antenna sits on land 300 feet above and 1000 feet horizontally from Lake Ontario. The QTH is in Scarborough, the eastern borough of Metropolitan Toronto. To the west, my signal must fight its way across 18 miles of city and climb the Niagara escarpment, 30 miles away, before getting anywhere. To the east, there is smooth sailing over the lake for 150 miles. My coverage very much depends on the direction.

For what it is worth, I can hear W8KAY, Akron, comfortably out of the noise when his beam is on K2IEG. With the four quads, he was just audible. I have gained the ability to work the weaker boys (AM) around Rochester, N. Y. and the tower types in downtown Hamilton. On two occasions I have worked dx stations to the west and south immediately after Dennis, VE3ASO, worked them. They reported that my signal was 2 S points better than Dennis's. VE3ASO has 150 watts and 40 elements in a reasonably good suburban location in western Toronto. I have 60 watts.

I have no 432-MHz gear yet, so I can't report on the performance of the 432 quads in actual operation.

Conclusion

The quad can serve all types of two meter hams. Those who have little in funds and space can make one quad. It will fit, and rotate, in the attic or sit in the corner of the apartment balcony. Tell the landlord that it is a work of modern art, which it will be if you do a good job.

The average Joe can put up four quads without stretching the budget much; it should do as well as about 24 ordinary elements in far less space.

The ambitious can put up 16 quads, which might be enough for moonbounce. The 48 quad elements should do as well as 96 ordinary elements. OH1NL had only 24 elements in front of a screen to work W6NDG. You can also use the antenna for earth-bound contacts, because it is small enough to put on a tower. A large parabola on a high tower presents nasty mechanical problems because of the wind.

Why use straight elements, when you can get more gain with quads? Give them a try.
. . . VE3DNR

The Expanded Quad

This article describes an experimental expanded quad which is practical to construct and which has considerably more gain and directivity than an ordinary quad of equal elements. A three-element version was constructed which works excellently on 10, 15, 20 and 40 meters.

The antenna originated in an attempt to construct the expanded (XQ) two-wavelength quad described by William I. Orr, W6SAI in his book on "Quad Antennas'. This book should be read by anyone who plans to construct a quad antenna. Orr developed the "XQ" quad from the "Lazy H". It had a side length of ½ wavelength and the three-element version was estimated to have more than 10 db gain over a dipole.

Originally a 3-element, 3-band quad was constructed in which the 10 and 15 meter elements were the XQ 2-wavelength loops. The 20 meter elements were conventional 1.0-wavelength loops. The 15 meter elements were loaded with coils to reduce the size, but they were still larger than the 20 meter ones.

After considerable experimentation, the

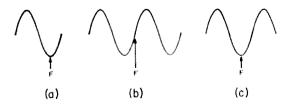

Fig. I. Feedpoints in the current wave for (a), an ordinary I wavelength quad, (b), a 2 wavelength quad, and (c), the I.5 wavelength expanded quad.

2-wavelength XQ was given up because of structural weakness and because the high impedance (2,000-3,000 ohms) at the feed point made matching too difficult.

During the experimenting it was noticed that the 10 meter XQ had a strong resonance and low impedance at a frequency near the 15 meter band. A check showed that the antenna was 1½ wavelengths at this frequency, and the feed point at the center of the bottom side had an impedance close to 50 ohms.

With the belief that this 1½ wavelength loop would approach the high performance predicted by Orr for the 2-wavelength XQ, the antenna was reconstructed to have 3-element, 1½ wavelength loops for 10 and 15 meters and the 20 meter was left as the standard quad.

All three bands have been satisfactorily matched to a single 52 ohm RGSU coaxial feed line. However, matching would have been simplified and the interaction less if a separate line had been used for the 15 meter antenna.

Numerous contacts and comparative tests have proven the 10 and 15 meter 1½ XQ's to be very effective. In over 90% of the contacts the S-meter rating received was better than could be given to the contact even though many of them used kilowatt linears in comparison to the 300 watts of the TR3.

Don is a professor at Texas A and M university (Phd Chemical Engineering, Iowa State). He has operated as HC2WH in Quayaquil, Ecuador.

The directivity, front to side and front to back ratios are noticeably better than those of the 20 meter quad which was used for comparison. It is believed that the gain of the 1% XQ is close to that esti-

mated by Orr for the 2λ XO.

An added bonus is that the 15 meter 1% antenna works very well as a 1/2 folded beam for 40 meters. This was observed after the antenna was erected so no attempt has been made to match it for better SWR or front to back ratio. As it is the SWR is 2.5 at 7.3 mc. and 1.05 at 7.2 mc. The element spacing constructed for 15 meters is much too close for 40 meters and a compromise should be made for more emphasis on the latter band.

Since the 1% XQ has performed so well on 10 and 15 meters, a 20 meter version has been planned. In the existing antenna, the spacing between the 15 and 20 meter wires is about 8 inches and there is considerable interaction when using a common feed line. With the 11/2 XQ for both 15 and 20 meters the spacing will be 3½ feet and the interaction should be greatly reduced.

With existing quad antennas, the 10 and 15 meter elements can be readily converted to the 1½ XQ for improvement in DX operation.

The 20 meter 11/2 XQ requires a side of 25 feet and spreaders 18% feet long. However, this is conservative when compared with some of the beams having 50 ft. booms and weighing 150 lbs. or more. A full size 40 meter quad at W3APO has 25 ft. fiberglass spreaders.

Theory

The reader is again referred to the book on Quad Antennas or the Antenna Handbook for the theory of the XQ and the detailed discussions of quads. Fig. 1 shows the feed-points in the current wave for (a) an ordinary 1.0λ quad, (b) a 2.0λ XQ and (c) the 1.5λ XQ, when the feed is at the center of the bottom side. The impedance of the quad and the 1.5\(\lambda\) XQ is usually between 40 and 75 ohms, while the 2.0x XQ will be in the enighborhood of 2,000-3,000 ohms. A % wave matching section may be used to reduce the high impedance to that of the line.

Tne ends of the quad are in phase and can be electrically joined, but the 1½ XQ

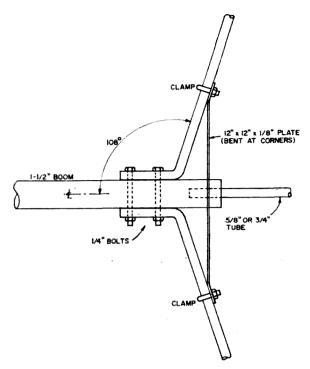

Fig. 2. Attaching the spreaders to the boom.

antenna ends are out of phase and must be separated by an insulation.

The 15 meter antenna works on 40 meters since 21 MHz is a third harmonic of 7.0 MHz. Actually if the antenna resonates at 21.4 MHz at 11/2 wavelengths it will resonate at 7.14 MHz as a 1/2 wavelength antenna. Experience has shown that the tuning is broad enough to cover the whole 40 meter

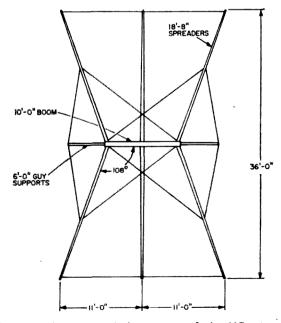

Fig. 3. Side view and dimensions of the XQ.

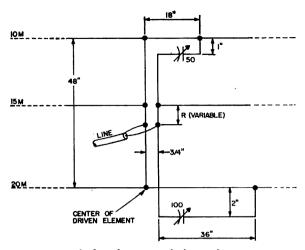

Fig. 4. Match for the expanded quad.

Construction

A construction description will be given for the 3-element, 3-band 1½ XQ antenna. Since it also works on 40 meters, it is actually a 4-bander.

Although a 4-element antenna of this type would give a slightly better performance, it is doubtful if the additional cost, labor, and wind risk is justified. On the other hand a 2-element version would be easier to construct and should have a gain better than 7 dB on all bands except the 40 meter band which would have a gain of 4 or 5 dB over a dipole.

No. 14 solid enameled copper wire is used for the antenna and a little over 8 lbs. is required. The loop sizes are as follows:

Frequency	Director	Driver	Reflector*
14.3	96'	100'	100'
21.4	64'3"	67′	67'
29.0	47'6"	49′6″	49'6"

*Reflectors are kept the same size as the driven elements to minimize spreader length. Either stubs or coils may be used for tuning.

Spreaders

The four front spreaders should be 17'9", the center ones 17' 9", and the back ones 18'8" long. They should be fairly stiff because of their length and preferably made of fiberglass-plastics. Since it is difficult to find bamboo this long, a combination of 1½" or 2" O.D. aluminum tubing and bamboo may be used. The bamboo should be covered with fiberglass plastic or it may be coated with butyl-aluminum roofing paint. Measurements indicated that the aluminum

paint had no electrical significance.

Boom

A ten foot length of galvanized steel or aluminum electrical conduit is suggested. This should be 1¼" or 1½" nominal pipe size or a 2" O.D. stiff aluminum tube could be used. The boom is extended at each end with 6 foot lengths of ¾" or ¾" O.D. light-weight tubing to serve as terminals for attaching the cross-bracing cards.

Assembly

Assembly of this antenna is quite an engineering feat. It was found convenient to attach the boom to a tilting mast in such a way as to permit rotation for access to the spreaders. The spreaders may be attached to the boom with purchased spiders. However, the author used sections of aluminum tubing as part of the spreaders and these were flattened and bolted to the boom as shown in Fig. 2. One foot square stiff aluminum plates were used for bracing.

Fig. 3 shows a section through the boom and center element. This is a diagonal section extending to opposite corners of the quad. Cross bracing with 150 lb. test nylon cord is used to increase strength and the ends of the spreaders are connected with it to hold the proper spacing. For clarity wiring is not shown on the figure.

Adjusting for frequency

Before attaching the connecting network each element was adjusted for proper frequency with a grid dip meter. The exact frequency was obtained by picking up the signal on a receiver. The driver elements were adjusted to 14.3 MHz, 21.4 MHz, and 29.0 MHz. The directors were adjusted to 14.9 MHz, 22.4 MHz and 30.3 MHz. Small tuning coils 2½" diameter, and having a length of wire of about 4% of the element, were used to adjust the reflector frequencies to 13.6 MHz, 20.4 MHz, and 28.0 MHz. Tuning stubs could be used if preferred.

Connecting to the feed line

A single RG8U, 52 ohm, feed line was used and this was connected to the three antennas as shown in Fig. 4. The 48" long header was constructed of No. 12 stiff copper wire and spaced ¾" with micarta in-

sulators. Gamma match connections were made to the 10 and 20 meter antennas and a direct connection was made to the 15 meter antenna. The line was connected to the header about 8" below the 15 meter antenna and the distance was varied to serve as a means for tuning.

The gamma match lengths and capacitances are approximate and are varied to obtain the best match. The values are affected by element spacing, proximity of the band loops, and height above ground.

Temporary variable condensers were used in the gamma matches. When tuning was complete they were replaced by short lengths of RG58U coax experimentally cut to give the same match. These were then sealed to keep out moisture.

Although the SWR is the final test, it is desirable to use an antennascope or impedance meter to make the matching adjustments. The antennascope construction is described in the "Radio Handbook" published by Editors and Engineers.

The method used for matching the 15 meter antenna to the line was made necessary by the interaction between it and the 20 meter quad antenna. With 1½ XQ

should be easier.

Since the gamma match lengths, capacitances, and the feed point are all interacting variables, considerable adjusting is needed to obtain a low SWR for all bands. However, the gamma lengths are not very critical and the 10 meter adjustments are almost independent of the 15 and 20 meter settings. So, after a preliminary adjustment of the capacitor on the 10 meter gamma, an optimization of the 20 meter capacitance and the feed-point setting (R) will bring the system to a fairly close balance.

The final SWR readings after the antenna was raised to 40 feet are shown below. These could have been improved by tuning with the antenna further from the ground.

Freq. 7.3 7.2 14.4 14.2 21.45 21.3 28.5 29.0 SWR 2.5 1.05 1.3 1.75 1.1 1.8 1.6 1.2

The results obtained from this antenna have repaid the trials and tribulations of building it. This includes repair after a windstorm blew it into the trees and a broken arm caused by a rotten ladder breaking under me.

An Inexpensive DX Antenna

Howard Krawetz WA6WUI 654 Barnsley Way Sunnyvale, Calif.

The increased activity in our ham bands has forced many good amateurs to use high gain directional antennas to obtain good solid contacts. The cubical quad antenna described here is quite directional, has high gain, and is inexpensive when compared to other beams (total cost is about \$30).

The antenna is mounted with spreaders running horizontally and vertically rather then diagonally. This enables the metal spider brackets to be welded with greater ease and may also add some strength to the assembly. The spider brackets should be made of %" x ½" x 2' aluminum angle (4 each required). Weld each pair on centers and at right angles. The spider to boom bracket

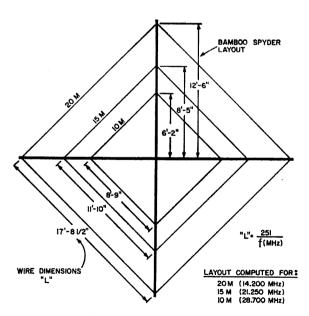

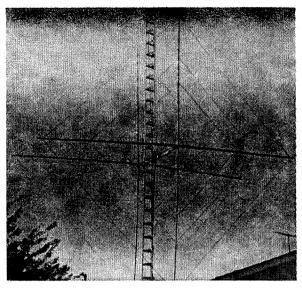

Fig. 1. Complete layout of the three band, two element quad; bamboo poles and a wooden mast provide very economical construction.

should be made of %" x 1" x 2' aluminum angle (2 each required). Weld in the center and at a right angle to the ½" wide legs. The metal may be obtained from a junk yard, some supply houses or any welding shop; take the materials to welding school or high school metal shop to be welded.

The boom to mast support bracket should be made of %" x 1%" x 2' aluminum angle (2 each required). These two pieces should also be welded to each other at right angles and on centers (see figure 3).

The boom is made of 2" x 2" lumber. One piece is 11 feet long and the other is 6 feet long. These two pieces should be nailed together with the shorter piece centered below the longer piece.

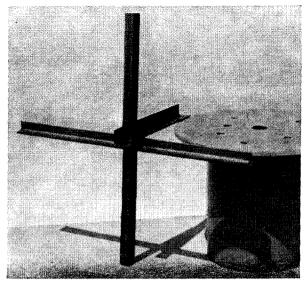

Center the aluminum boom to mast bracket on the boom, drill at least 8 nail holes through the horizontal leg and nail the assembly together.

Obtain the bamboo from a carpet store as carpets often come wrapped around bamboo poles. Try to get unsplit, straight poles 13' long and the thinner the better. You will need 9 poles and they should not cost over 25 cents each.

Cut up a couple of coat hangers into 3" lengths and form into wire hooks as shown in Fig. 3 inset.

Lay out the bamboo to the dimensions shown in Fig. 1. Drill holes through one side of the bamboo and install the wire hooks into 3 legs of the spider. On the fourth leg drill the holes all the way through the bamboo 1" above and 1" below the laid out dimensions for each spider assembly.

Assemble the bamboo to the spiders using

Construction of the homemade spreader assembly. This bracket is welded together from pieces of aluminum angle.

2 small hose clamps for each pole. Most auto stores have an ample supply of hose clamps in assorted sizes.

For each band, attach one end of the wire through the upper hole on the fourth leg. Wrap the wire around the spider and attach the end through the bottom hole. Attach the feed line to the wire ends on the driven element and solder. Short the wire ends together on the reflector element. Tape over the wire hooks to make sure the wire stays in place as it has a tendency to stretch with time.

Assemble the spiders to the boom with large hose clamps. (This is the toughest part.) Space the elements as shown in Fig. 3.

The last bamboo pole is the stabilizer. Cut it 9' long, drill a small hole through two small hose clamps and screw them to each end of the pole. Attach the stabilizer

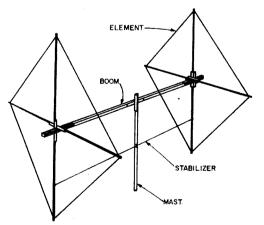

Fig. 2. Overall view of the two element quad showing the layout of the boom, mast and stabilizer.

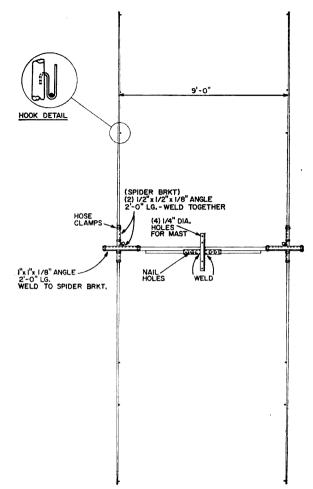

Fig. 3. Constructional details of the two element, three band quad.

about 8' down on the fourth legs between the elements and parallel to the boom.

Number 17 bare stranded copper wire is adequate for a QRP station, but where higher power is used, #12 copper wire should be employed.

Feed the array with 52 ohm coaxial cable. We found that two of the bands could be fed with the same feed line without appreciable loss, but the other band had to be fed with a separate feed line; this array has 10 and 15 meters on the same feed line with a separate line for 20 meters. It was also found that tuning stubs on the reflector were not absolutely necessary and were omitted from the installation.

We have received Q5 signal reports from Austrailia, New Zealand and Japan with 70 watts on the 10 and 15 meter AM bands. The antenna has been mounted on a 20 foot tower with good results, but much better results are obtained when mounted on a 40 foot tower.

. . . WA6WÜI

The Miniquad

The Miniquad has two unusual features. 1) It is of all-metal construction¹, thus eliminating the problems of treating bamboo and welding spiders, only to have the whole antenna come tumbling down in a year or two, and 2) It is miniaturized², taking up less than half the space of a normal two-element quad. Added features of the Miniquad are its low cost, extremely light weight, and general ease of construction. The Miniquad can be built from parts of an old beam, or it can be fabricated from scrap aluminum. It is light enough to be turned by a low-priced TV rotator.

Theory

The antenna illustrated in Fig. 1 is essentially a two-element quad with .12 wave-

length spacing. Note that the two loops are insulated from the booms and thus from each other. The horizontal dimension is .25 λ , while the vertical dimension has been reduced from the usual .25 λ to .125 λ . The difference is made up with loading coils at the bottom of each of the two loops. The Miniquad is thus rectangular, rather than cubical, in configuration. The 52-ohm transmission line is inductively coupled to the loading coil on the driven element.

Construction

The Miniquad lends itself to much flexibility in construction. The original version was built at almost zero cost from the parts of an old Telrex beam. However, eight tenfoot sections of tubing of almost any mater-

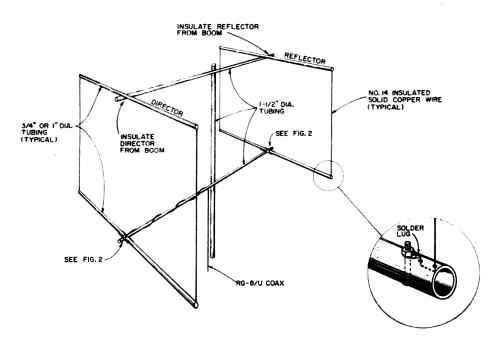

Fig. 1. Construction of the miniquad. For operation at 14250 kHz, element spacing is 100 inches, the horizontal supports are 208 inches long and the vertical distrance between the horizontal supports is 104 inches. The upper supports are insulated from the boom with standoff insulators.

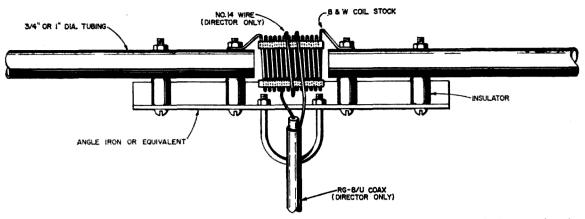

Fig. 2. Loading coil for the miniquad: a piece of coil stock two inches in diameter and three inches long is about right. The feedline is coupled into the antenna with a two or three turn loop around the loading coil.

ial and any diameter provide elements. Center mounts can be constructed of aluminum angle irons with standoffs as insulators. Masts and booms are made of TV masting. Standard antenna hardware is used for mounting the booms to the mast.

The vertical portions of each loop are of insulated number 14 solid copper wire, of the type commonly used in electrical housewiring. The wires may be attached to the ends of the horizontal elements by any convenient means. The wires should be tightened so that the top and bottom elements "bow" slightly toward each other.

Coils

The exact number of turns for the two loading coils and the coupling link depends on many factors and therefore differs for each Miniquad. The original twenty meter Miniquad has coils each made of about three inches of two-inch-diameter B&W coil stock. The driven element coil should be grid-dipped for the center of the desired operating band. Be sure to make this measurement in the absence of stray inductances.

The reflector coil is adjusted, in the usual manner, for either maximum front-to-back ratio or best forward gain. Note that no tuning stub is required on the parasitic element of the Miniquad, as the element already has a loading coil. Thus the reflector coil will simply have somewhat more inductance than that of the driven element.

The 52 ohm coax is coupled to the driven element by winding about five turns of insulated #14 solid copper wire around the loading coil. Since only this link is across the transmission line, a very low standing wave ratio may be obtained by proper choice of the number of turns.

Performance

The SWR of the twenty meter Miniquad used at WA2APT is less than 1.5:1 for the entire band, and close to 1:1 over much of the band. Transmitter output tuning is quite broad, with retuning required only for large frequency changes. Front-to-back and front-to-side ratios seem quite satisfactory.

Using 150 watts input on twenty meter CW and SSB, over 40 countries on all continents have been worked in just a few months of occasional operating, using the Miniquad at a height of only twenty-five feet above ground. All qualitative indications suggest that the Miniquad comes close in performance to a full-sized quad. Who says you can't get something for nothing?

A Full Size 7 MHz Rotary Cubical Quad

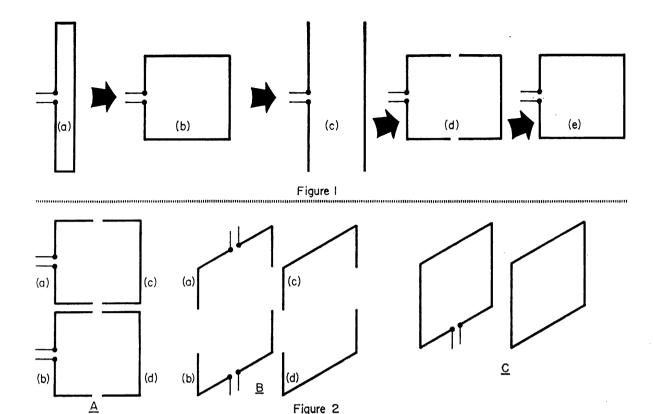

Have you been on 40 recently? Did you notice how much harder it is to consistently work DX with a moderate antenna? Here is the solution to your problem, but you must have the time, patience, cash, a large backyard and no neighbors! Although this antenna was erected way out in the country on a farm in southern Wisconsin, it has attracted considerable attention. The permanent residents of the farm have been continually asked about it and passing airplanes occasionally drop down for a closer look. The volume of this antenna is only

The full sized forty mater cubical quad. Compare its size with the barn in the lower right hand corner.

about 36,750 cubic feet, but that is enough to capture lots of DX! Compare the size of this antenna with the shed in the picture. This is not the first 7 MHz cubical quad, but it is one of the very few in existence; K6PRU used one several years ago and recently W8BAR put one up.

If one takes a simple half wave folded dipole antenna (0 dB gain), stretches it into a square or rectangle in a horizontal plane, and feeds it at an appropriate place, 3 to 6 dB gain can be obtained (Fig. 1a and 1b). This is similar to taking a 2 element parasitic beam and bending the elements 90° at a point ¼ of their own length back from each end and joining them (Fig. 1c, 1d and 1e).

If two identical antennas are properly spaced, 3 dB additional gain can be obtained; theoretically, this arrary has 6 to 9 dB gain. Suppose, however, for convenience in feeding the elements of Fig. 2A (a and c and b and d) are not connected mechanically as in Fig. 1e but are connected inductively and capacitively. Also, instead of connecting the two feedlines to a and b together, omit one feedline and connect a and b mechanically by moving the bent tips into a vertical position. Assume that the same degree of coupling can be obtained regardless of the type, mechanical or inductive. Do the same with c and d; the result is shown in Fig. 2C, the standard cubical quad. It can be seen that the radiating portions of the antenna have not been moved nor their length changed; only the method of feed has been changed. Thus, the gain should remain the same, about 6 to 9 dB.

Development of the cubical quad from the folded dipole in Figure 1 and into the two element quad in Figure 2. This development is completely explained in the text.

A full size 7 MHz quad requires supports for two squares of wire that are about 40 feet on a side and spaced 30 feet apart. A structure of several tons could conceivably be used to support these two loops of wire but a more practical way is to build a rotatable support system of minimum weight, bulk, and cost that will withstand wind, bird and ice loading.

Although I used a rather small 55 foot crank up tower, something heavier is advisable. The mast is a six foot length of 11/4" solid steel shaft; a surplus motor system with a gearbox and selsyn are mounted at the base of the shaft. The shaft is coupled to the motor through a slotted section of pipe mounted on the rotor. Right angle gears connect the shaft to a Rotobrake mounted on the side of the tower. A greased sleeve mounted in the top of the Tri-Ex tower acts as a thrust bearing. Just above the top of the tower a 24" x 12" x ¼" steel plate is mounted on the 1¼" shaft by means of four U bolt muffler clamps as shown in the photographs. On the back of this plate four home made 4" U-bolts made from 38" Redirod were installed. The 30' x 4" OD 0.06" wall aluminum boom is supported at its center by these four clamps. A sleeve of inner tube rubber around the boom restricts slippage of the boom during wind vibration and a semicircular sleeve of aluminum sheet on the outside of the rubber (on the clampside) prevents tight clamps from kinking the boom. A heavy ground strap grounds the boom to the tower and to a ground post. A bolt through the boom could have been used to prevent boom rotation but there was some possibility that this might weaken it at a critical point.

Additional boom support is provided by the boom guy system. A second steel plate is clamped on the mast just above the boom support plate (Fig. 4). A piece of pipe is clamped on the backside of this plate and holes were drilled at the ends to accommodate screw eyes. Guy wires of galvanized #9 wire run from these screw eyes to the boom tips where they are anchored with irrigation tubing clamps. These four guys hold the boom firmly in the horizontal plane.

Since the 6' steel shaft was too short, an extension of 134" OD water pipe, 6' long was mounted on top of it with two

^{*} Hq-Gain Antenna Products Corp., N.E. Highway 6 at Stevens Creek, Lincoln, Nebraska 68501.

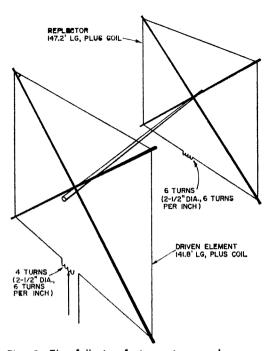

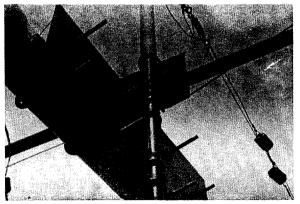

Fig. 2. The full size forty meter quad. bolts going all the way through both sections. To prevent boom sag, guy wires were connected between screw eyes mounted on top of the mast and the ends of the boom; turnbuckles permitted adjustment for minimum sag. The complete assembly is well balanced and spins on the ball bearing

mount with the twitch of a finger.

Many spider systems were considered, but the one finally adopted was developed from a suggestion of Roger Mace, W6RW. A piece of 24" x 12" x 1/8" (10 gauge) steel plate was bent 90° at the center. A piece of 4" ID water pipe was sliced into 1" wide rings; each of these was slit along one side. Two of these were welded to each plate as shown in Fig. 4.

On each side of the slits in these clamps an over-size nut was welded; a bolt could be run through these nuts to tighten the

Method of supporting the boom to the mast. This photo also shows part of the guy wire system used.

clamp snugly around the boom. Diagonal reinforcing bars of 1" x 44" steel strap were added as shown in Fig. 4. Two holes drilled at the base of the plate accomodate U-bolts; a 3" length of 1" wide, 4" thick angle iron is welded into the top of each plate flush with the 90° bend. Each section of angle iron has holes drilled in it for a U-bolt and was mounted so as to have one side flush with the other side of the angle plate as shown in Fig. 4. A thirty foot piece of 2" OD aluminum irrigation tubing was used for the central section of the support arms. Five-foot lengths of 1\%" OD tubes are telescoped inside the ends of this piece. Twelve foot lengths of high quality bamboo are telescoped inside the ends of the aluminum to give an overall length of about 56 feet. For maximum strength these bamboo poles should be wrapped with a layer of surgical gauze and coated with fiberglass.

The tubing to tubing and tubing to bamboo joints are made as shown in Fig. 4. Sleeves of sheet aluminum are placed over the arms where the U-bolts will grip them. Good quality hose clamps may be obtained from an automotive supply house for the joints. About 6 inches from the upper tip of each piece of bamboo the wood should be wrapped with tape, a hole drilled and a small pulley tied on. These two pulleys support the upper corners of the wire square and permit it to be lowered for adjustments; nylon cord is used in the pulleys.

In order to prevent the spider arms from breaking in the wind they must be properly guyed. Holes were drilled in the two 1" straps welded across the bottom of the spider plates and at the tips of two 5 foot pieces of 34" pipe; these pipes were bolted on as boom extensions. Nylon parachute cords run from the holes in the end of each boom extension to the tips of each of the four element arms. Three separate strands should be used in parallel for maximum protection. Likewise, four guys run from the other side of the element arms to an extra spider on the inner side of the boom (reserved for future additions). For further support of the arms, particularly when the wire square is lowered, nylon rope was run in a square around the bamboo arms 6 feet from their tips; the total arm guy system is shown in Fig. 5.

*Good quality bamboo will be shipped by the Sea and Jungle Shop, 4666 San Fernando Road, Glendale, California. They maintain a large stock of all sizes.

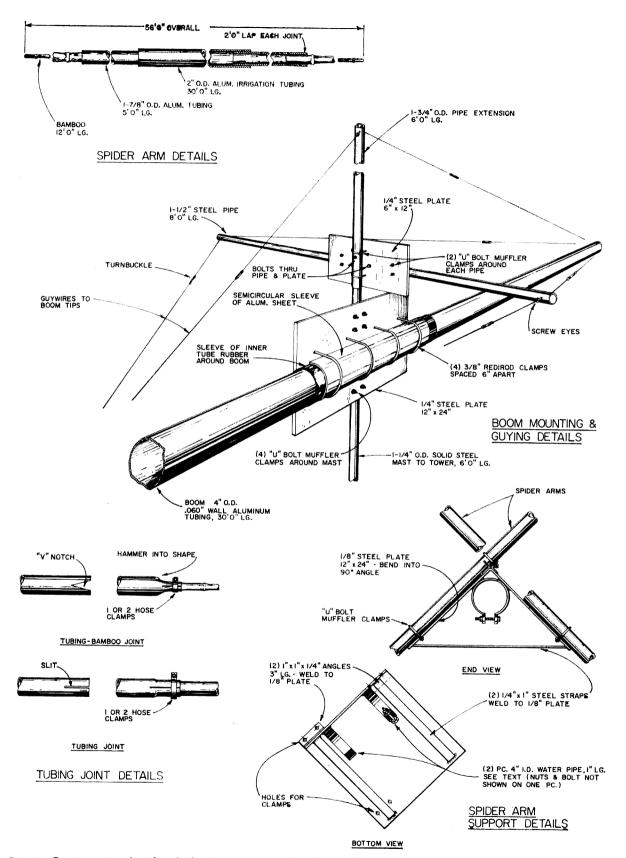

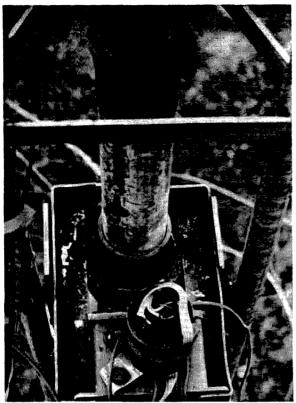

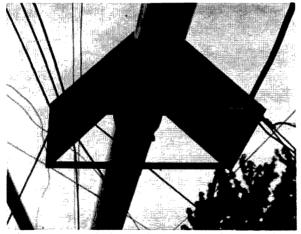

Fig. 4. Construction details of the forty meter cubical quad. This type of construction results in a light weight assembly that will withstand wind loading up to 60 mph.

Top view of the rotator mechanism. The mast is held in the slotted collar with a bolt. The selsyn may be seen in the foreground.

Assembly requires strategy but this leaves room for your own ingenuity. If you're in a hurry you may want to try the following. First of all, you need something to stand on 15 feet away from the tower and at least 20 feet high. I used a long ladder leaning against a truck, heavily guyed in

Closeup view of the spiders; this spider is midway between the mast and the end of the boom and is not used to hold the forty meter quad. It was intended for the additional of a full sized twenty meter quad at a later date. In the forty meter quad it serves as an anchor point for part of the guy wire system.

each direction. A large pulley is placed on top of the mast to haul up parts. Most of the antenna can be assembled by one person but two people make it a lot simpler.

The items are mounted in the following order: rotor, ball bearing, gears, thrust bearing, mast, Rotobrake, boom support plate, and boom guy plate. Then the spiders, guy extension arms, and boom guys with extra lengths of cord attached for manipulation from the ground. The boom is raised into place by pulley and then tied down to hang beside the boom support plate. The U-bolts, sleeves and rubber are added and the bolts tightened. The extra lengths of cord on the boom guys are used to pull the guys into place for anchoring; then they are temporarily tightened.

The four element arms are completely fabricated on the ground and their guys attached. One man can carry one up the ladder and tie it temporarily to the boom while adjusting the U-bolts and sleeves. However, it may be more convenient to have an assistant on the ground to hand you one side of the element arm while you manipulate the other side by means of a rope (don't use guy ropes tied to the tips of the bamboo for manipulation or you may break the bamboo). Make sure the pulley tips of the arms are on the ground side.

The other ends of the guy ropes are now fastened. At this point only the square of guy ropes between the individual bamboo arms will have one or two ropes unfastened 35 feet in the air. The extra spiders are 7.5 feet out from the center of the tower, but by wearing a lineman's belt and leaning way out from the tower, they may be reached to tie the guys on.

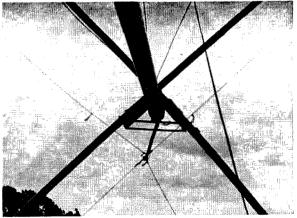

The second set of spider arms is now added. If convenient, the boom may be rotated around to put the other boom end above your ladder; the second set of arms and guys is then added in the same manner. The pulley tips of the bamboo are close to the ground and the guy rope between them is securely fastened. This guy carries more weight than the others and if possible, should be of heavier nylon rope. It should always be kept tight as it distributes the wind load more equally between the four diagonal arms.

When these guys have been adjusted and the other guys have been added to the pulley arms, the 4 boom U-bolts are loosened and the boom is rotated 180° on its own axis to put the pulley tips high in the air (if you have a derrick truck you can work on each part of the antenna without the need for boom rotation). The remaining guys are then fastened. The wire elements are prefabricated on the ground and may be pulled up with the pulley ropes and tied down. In my case it was found convenient to hang a nylon rope from the boom tip to support the heavy gamma match and RG-8/U coaxial feedline.

Considerable adjusting and tinkering was done with the elements after the antenna was mounted on the tower. The final dimensions include a coil at the bottom center of each element for length adjustments. Little efficiency is sacrificed by using coils and they are much more convenient than changing large lengths of wire. The dimensions of the elements are given in Table 1.

The resonant frequency was 7.0 MHz when the boom was 25 feet off the ground; at 56 feet the resonant frequency was 7.2 MHz with the following SWR across the land: 7000 kHz, 1.8; 7100 kHz, 1.4; 7200 kHz, 1.25; and 7300 kHz, 1.4. The resonant frequency shifted about 50 kHz during rotation due to proximity of nearby objects, but this was of little consequence because of the broadbanded nature of this quad. The gamma match uses two #12 wires 4.6 feet long and spaced 6 inches apart with plastic spacers; a series 200 pF capacitor was used to tune out the inductive reactance of the gamma match.

This quad gave very good results in the 1961 World Wide DX contest and 1962 ARRL DX contest. Africa was worked via long path and European hams were heard on the long path around 1400 GMT; DX worked included HV1CN, FB8XX, TU2AL,

The spider supports used at the ends of the forty meter cubical quad.

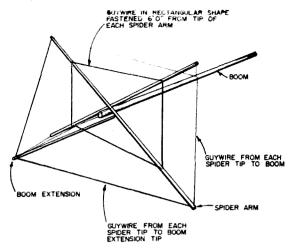

Fig. 5 Guying system used with the spider arms. Without this system the arms will break in winds of 30 to 40 mph.

VK5XK/VK9, EP2BQ, VS9AAC, and ST2AR. The quad compared very favorably with full size two element beams of similar height in the USA but no local beams were available for comparison. JA's were worked one after another in the morning and stations running 5 to 20 watts from several continents had good 559 and 569 signals; Europeans have been as strong as 40 db over 9 on a 75A4. The quad consistently got very good signal reports and often, "First W9 on 7 MHz".

The front to back ratio runs from 5 to 40 db depending on the direction, angle of radiation and skip characteristics. Numerous observations of 7 MHz broadcast stations and hams showed average gains of two S-units or better over a 1000 foot longwire aimed at Europe. Nearly all work has been on CW with 900 watts, but with a borrowed SSB exciter all continents except Asia were easily worked.

The antenna has stood up well in 50 to 60 mph winds, snow, and ice as long as all guys were kept tight; if the guys are not tight the arms will break in winds of 30 to 40 mph. This antenna is a joy to operate with on 40 meters, but you must take a bit of time to build and maintain it.

I wish to express my appreciation particularly to my tolerant landlady, Mrs. Ellen Richardson, to Alice and Otis Onsrud (Mr. Onsrud contributed the expert welding), Tom Leffingwell, and Donald Weinshank. Also to W4VRD, W6RW, K9ELT, K9KNC, W9SZR, and to all the others who have helped.

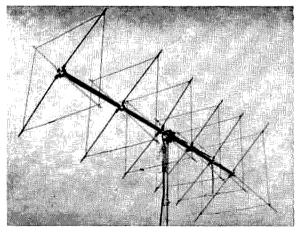

. . **K**6DDO

Experiments with Quad Antennas

Over the past few years I have constructed a number of antennas, largely based on data collected from the various ham magazines. In most cases however, I wasn't completely satisfied with the results; also, the dimensions varied from one article to another and the gain figures given by the authors seemed to be somewhat excessive.

I decided that the only way I was going to get a proper answer was to conduct a little basic research. With the few instruments that I have at my disposal, and a lot of cut and try, I think I can now provide some useful information on the construction of cubical quad antennas.

My first experimental quad antenna was designed for 145 MHz. This antenna was designed in such a way that I could vary the dimensions, spacing and height from the ground. Since I didn't have a lot of exotic antenna testing equipment, I made do with what I had. The resonant frequency of the elements was found with the aid of a grid-dipper and a communications receiver; the front-to-back ratio, minimum radiation angle and attenuation off the sides of the antenna were determined with three separate field strength meters. In addition, an antennascope was used to measure the input im-

The six element quad for two meters is centered on 145 MHz. This antenna has a boom length of 144.5 inches, just a hair over twelve feet, and has provided excellent results on two meters.

pedance to the quad and an SWR meter used to check the match.

With this simple test equipment I closely examined a three element quad for two meters and the effects of element spacing, height above ground and various elements dimensions. To insure that the results were not just casual but repititive, the tests were conducted over a three month period and have been repeated three times; in each case the entire antenna was completely disassembled and re-assembled. After I had completed all the tests on the 145 MHz quad, I used the experimental data to develop a three element three band quad for 14, 21 and 28 MHz.

Obviously, to construct an antenna for three different bands, I had to make compromises to obtain optimum results on all three bands. During the course of my experimentation I was able to establish that when a reflector was adjusted by means of a stub on the lower part of the square, the antenna became asymmetric and lost considerable gain in the horizontal plane. Therefore, two stubs should be used to adjust the reflector and other parasitic elements; one on the upper side of the reflector and one on the lower side. In addition, these two stubs should be adjusted together. This solution practically precludes adjusting an antenna for 14, 21 and 28 MHz, so I completely removed the stubs and made all the sides of the quad perfectly symmetrical. I also found in the course of my experiments that the alignment between the wires of the various elements is very important.

After completing the experiments with the model antennas, I built a full size three element quad for 14, 21 and 28 Mhz. This antenna has been placed on a support projecting 5 meters (about 16½ feet) from the roof of my house. This antenna is fed with a single transmission line; two relays mounted in a water-tight box switch in the proper radiator when I change bands. It is highly advisable to use a ¼ wavelength of transmission line (or an odd multiple) between the relay switch box and the radia-

Quad Dimensions

Band	10 Meters	15 Meters Total Length of Wire	ZO Meters used in each element	2 Meters	
Reflector	1079 cm (424.8 in)	1470 cm (578.7 in)	2204 cm (867.7 in)	216 cm (85.0 in)	
Radiator	1029 cm (405.1 in)	1403 cm (552.4 in)	2103 cm (828.0 in)	206 cm (81.1 in)	
Director	978 cm (385.0 in)	1333 cm (524.8 in)	1997 cm (786.2 in)	197 cm (77.6 in)	

Spacing between elements: on the tri-band beam for 10, 15 and 19, and 20, the director is spaced 260 cm (102.4 in) from the radiator; the reflector is spaced 230 cm (90.6 in) from the radiator. For the six element two meter quad all spacings are in reference to the radiator and are as follows: reflector, 31 cm (12.2 in); 1st director, 29 cm (11.4 in); 2nd director, 63 cm (24.8 in); 3rd director, 96 cm (37.8 in); and 4th director, 148 cm (58.3 in).

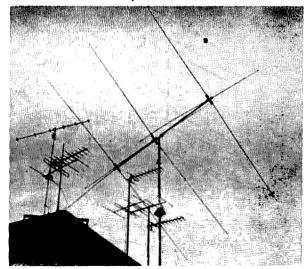

tor element. You definitely should *not* tie the three radiator squares together to facilitate feeding by a single transmission line; the gain and directivity are completely destroyed.

Mechanically the beam was constructed by using a boom of extra-light steel tubing on which three cast aluminum cross-pieces are threaded. Bamboo poles were used to support the wires. At the points where the wire squares are fixed, stainless steel springs have been mounted to keep the wires taut and in alignment without subjecting the bamboo supports to flexing. These springs also compensate for the lack of symmetry of the poles after they are mounted on the boom. After the wires and stainless steel springs were mounted, all the bamboo poles were given a coat of protective paint.

Where the poles are attached to the crossarms, a small sheet of thin rubber 6 mm thick (about 14 inch) has been inserted to make the joint more elastic. The poles are then fixed in place with galvanized U-bolts. The preparation of the wire squares requires the utmost in accuracy; the data shown in the following tables should be followed as closely as possible. The easiest way to accomplish this is to unwind the wire, measure a length 20 cm long (8 inches), form a small eyelet in the wire and solder it so it provides a reference point for the subsequent eyelet. Each side of the square is carefully measured until the whole square has been made; the first length of wire is used to close the last side with a solder joint. Close attention to this procedure greatly facilitates the final assembly, and permits easy installation of the eyelets at the corners over the stainless steel springs. The same method may be used for the construction of a 144 MHz quad, but for the two meter version the bamboo should be replaced with a material that has better rf characteristics.

The results obtained with this antenna are best illustrated by comparing it to a multiband commercial unit. The front-to-back ratio is not maximized because of the compromises made in dimensions to permit optimum operation on three bands. However, on 20 meters the front-to-back ratio is on the order of 22 dB. The vertical angle of radiation appears to be lower than that of a two element quad, but unfortunately, comparative tests are difficult to evaluate in terms of radiation angle and front-to-side ratios. The actual operating results have been excellent; with only 16 watts input on 14, 21 and 28 MHz, I have had excellent results working DX stations.

I have also been extremely pleased with the results obtained with the six element two meter quad; this antenna has consistently out-performed large commercial antennas installed by local amateurs.

The three element quad for 10, 15 and 20 meters. The SWR on all bands is less than 1.5:1, even at the band edges. On 14.00 and 14.35 MHz for example, the SWR is 1.4:1, at 14.18 MHz it is 1.2:1; at 21.00 and 21.45, the SWR is 1.2:1, at 21.23 it is 1.1:1; and on 28.2 and 29.5 the SWR is 1.4:1, at 28.8 it is 1.2:1. SWR checks with both Heathkit and Jones Micromatch bridges provided almost identical results.

The Half Quad Antenna

A muscular version of the inverted V dipole

Thirty some odd years ago, E. J. Sterba developed a form of stacked dipole antenna which bears his name. Although the Sterba curtain is not too popular with radio amateurs, it is, none the less, an excellent antenna. The Sterba, as you no doubt know, is the grandaddy of some antennas that enjoy great popularity today.

The lazy H, a simplified version of the Sterba in its basic form, is one of the descendants of the Sterba, and was introduced to the amateur world by W6BCX. From the lazy H, the same gentleman, W6BCX, developed the bi-square by combining the half wave elements in the form of a square. The bi-square dimensions, particularly at

the lower frequencies, become rather ungainly mechanically, so it was inevitable that someone would find a way to reduce the size of the half wave sides and still retain reasonably good gain. We know this reduced size bi-square, with one quarter wave length sides, as the cubical quad. Now, let's take the quad and reduce it in size by slicing it in two, leaving only the top half. This remaining half, for want of a better name, becomes a half quad.

The main advantage of the half quad is that it can be erected for the 40 and 80 meter bands without resorting to the use of broadcast station size towers. The half quad employs wire elements, supported in

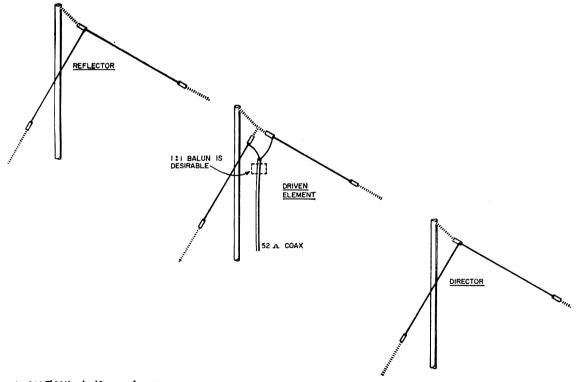

Fig. I. WØSII's half quad antenna.

with the new improved

SWANTENNA

The only remote controlled band switching mobile antenna on the market.

5 BANDS-500 WATT

POWER RATING

We are pleased to offer the new band switching deluxe Swantenna as part of the Swan line. Two of the major improvements are the use of GE Lexan® in the center coil support that makes it virtually unbreakable, and the new light weight stainless steel whip. The higher Q of the Swantenna and the gold plated switching contacts provide greater radiation efficiency and field strength than most coil changing designs. Thus with the new improved Swantenna you achieve the ultimate in mobile operation; a high efficiency antenna system plus band switching while driving.

Antenna Connector

Disconnect your antenna from bumper mount in seconds. Made entirely of stainless steel. Noise \$3.25

DELUXE BUMPER MOUNT

The most important development in mobile antenna mounts in years. No chain to break, no clip to stretch. Made of highly polished cast aluminum. Complete instructions illustrate how to fit this deluxe mount to the exact contour of your bumper.

contour of your bumper, providing the strongest, best looking mount for your mobile antenna.

Half Quad Dimension

Half Quad Dimension

7.1 MHz 7.2 MHz 3.8 MHz 3.9 MHz Reflector 69'10" 68'3" 129'2" 126 Driven Element 66' 651 1231 120' 62'8'' 41,3, 106'10" Director

One quarter wave length, for element spacing, (In Feet) = $\frac{246}{\text{Freq (MHz)}}$

the center with a single pole. The elements are slanted down toward ground at an angle of approximately 45 degrees (See Fig. 1). The parasitic elements are attached to the poles with small insulators, and the driven element is constructed and attached to its pole in the normal inverted "V" fashion.

The two or three element version of the half quad, with one quarter wave spacing between elements, will give good gain and allow the array to be fed directly with 52 ohm coax cable. With one quarter wave length spacing, the feed impedance of the half quad, using the two element version with a driven element and reflector, will be about 60 ohms. The three element half quad will give a feed point impedance of approximately 30 ohms. The gain of two element half quad is 4.5 dB, and for the three element half quad, 8 dB.

The half quad at this QTH is the 40 meter size, suspended from 50 foot poles, and oriented on Australia. The reports on SSB, received from the VK's, range from S-5 to S-8, a very respectable performance from a horizontally polarized antenna with an average height of about one quarter wave length above ground.

As an added note, and with apologies to an old acquaintance Dr. John Kraus, the W8JK Flat-Top array can be rigged in the Half Quad manner, when a bi-directional pattern is desired.

Inexpensive Equipment Feet

The "Self-Stik Flan-Tabs" are an excellent and cheap source of scratchproof feet for small equipment cabinets, mini-boxes and the like. They are green flannel covered discs with a pressure-sensitive adhesive on the back and come in two sizes, % inch and % inch, 32 to a card for 29c in dime stores.

. . . Edwin Hill W3URE

The Three Element Quad

It is certainly not an "old wive's tale" when someone speaks about the performance results of the two element cubical quad. The gain is comparable to that of a three element yagi. From personal experience, the front-to-back ratio ranges from 25 to 30 dB, with the front-to-side ratio reaching as much as 40 dB. For the size of the antenna it packs a mighty punch in the roughest of pile-ups, and amateurs around the world will attest to its performance. Another favorable aspect of the quad is the relatively low construction cost.

The three element quad as seen from K8YIB's house shows the director, the driven element, and the reflector. The boom consists of three inch irrigation tubing and the spreaders are bamboo.

As we all know, most amateurs are never satisfied with their antenna, so we decided to go one better, and try a three element quad. There was very little information available on this type of antenna, nevertheless the problem of design and construction was undertaken.

Design

The dimensions for the three element quad were taken from WØAIW's dimensions for his four element quad. It was thought that we had to start somewhere, and Lee's figures looked good. Originally the boom length was twenty-five feet, but after running some tests on the air with local and out-of-state stations, it was decided that the front-to-back ratio was suffering badly. Thanks go to WAØIOR, Hal, whose suggestion to shorten the boom length was a great help in the final success of the antenna.

Construction

Spreaders: Fiberglass poles make excellent, durable spreaders, but are guite expensive. Bamboo poles also suffice, but do not weather well unless they are protected. A few coats of Spar varnish will last several years, but if the poles are fiberglassed, they will last indefinitely. Fiberglass resin and fiberglass cloth are available at most boat centers and sport shops. The bamboo poles were cut to a length of thirteen feet, and wrapped from the small end to the butt with three inch wide fiberglass cloth. About half a quart of resin was mixed at a time, and applied with a paint brush. About two days are required for the poles to dry.

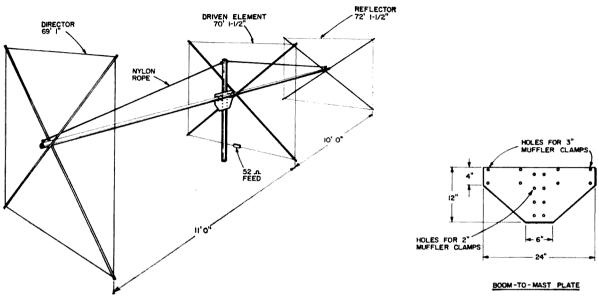

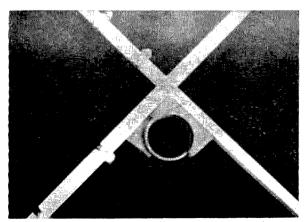

Fig. 1. This three element quad for twenty meters provides extremely wide bandwidth as indicated by the low SWR throughout the band. The construction of this quad is straight-forward and only requires a boom length of 21 feet.

Supporting crossarms: Three foot sections of one inch angle aluminum were used to hold the poles to the boom. The muffler clamps used between the angle stock and the boom are three inch. The bamboo poles are held to the angle aluminum by one and a half inch hose clamps.

Boom: The boom consists of twenty-one feet of three inch irrigation tubing. The spacing from the reflector to the driven element is ten feet, and the distance from the driven element to the director is eleven feet.

The supporting crossarms.

Stringing the elements: Number fourteen wire was stretched out and marked at 69' 1" for the director, 70' 1½" for the driven element, and 72'1½" for the reflector. After the crossarms had been assembled, the spreaders were staked out perpendicular to each other, and each element was strung.

Assembly and tuning: Each element was fastened to its respective position on the boom, and 52 ohm cable was attached directly to the driven element. Tuning stubs were fashioned out of #12 wire and fastened to the director and reflector. The antenna was raised to approximately twenty feet, and the stubs were adjusted to give maximum s-meter readings on a receiver beneath the antenna.

Repeated comparisons with a nearby station, on the long and short haul DX, seem to indicate that the three element quad is comparable to his four element yagi. The front-to-back and front-to-side ratios are as good if not better than the two element quad.

Over 200 countries have been worked in the last six months, and good success has been experienced in the pile-ups.

. . . **K8YIB**

A Light Four Element Quad for 20 Meters

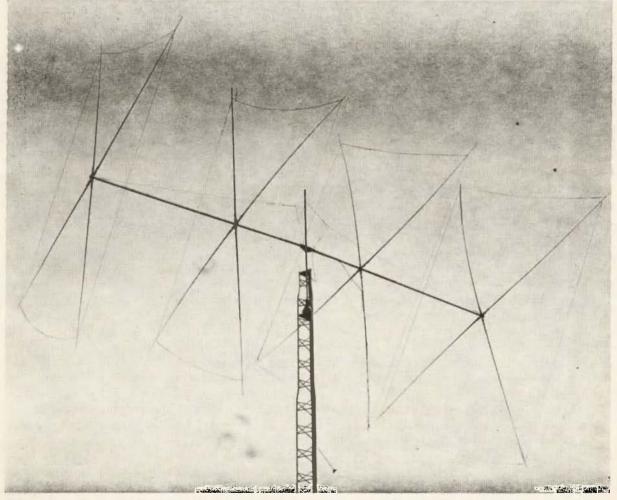

Now that Spring is here it's time to think about improving your antenna system.

Why the antenna and not the transmitter? Well it's easier to increase power in the antenna than it is to improve output power in the transmitter.

For example: If one ham in town puts up a quad that gives 10 dB gain, then another ham in the same town would have to increase his output power 10 times to get the same signal report. A 100 watt station using this same antenna would be as strong as his neighbor running 1,000 watts to a dipole.

A recent survey among leading DXers in the world shows that the six element beams and the four element quads put out the "big" signals.

Most people don't have the room or the money to put up a six element beam but

A tour element quad for 20 meters. This antenna weigns less than 50 pounds and has witnstood winds up to 80 miles per hour.

MAY 1967

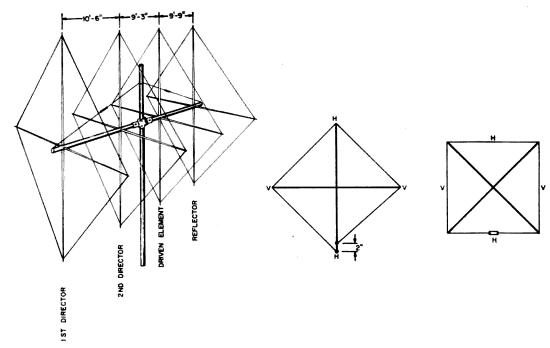

Fig. 1. Overall view of the four element quad for 20 meters; the total boom length is nearly 30 feet. Either diamond or square construction may be used as shown on the right, but the square model requires insulators—one in each element.

a four element quad doesn't take too much space and is considerably cheaper than the beam.

In the past, four element quads have been bulky, very heavy and parts were hard to come by. Today a four element quad can weigh under 50 lbs. By using lightweight fiberglass arms (16 of them) each weighing only a pound and by using a lightweight aluminum boom and using aluminum braces to mount the arms to the boom all totals up to a lightweight four element quad that can be supported by most towers capable of supporting a tri-band beam.

A 2" x 30' x .065 wall tubing spec. 6061ST-6 boom will support the lightweight arms and has a lower wind resistance than the 4" boom used in the past.

The least expensive arms for a quad are made of wood or bamboo. These arms can crack, split, warp and are easily broken during construction or by the wind after construction.

Commercial fiberglass is now available within the price range of the average income. This fiberglass is made especially for quad antennas and is manufactured by several companies. These lightweight arms sell for about \$5 each or \$80 for the 16 arms.

Quad arm mounts are also available for around \$5 each or \$20 for the 4 mounts.

Boom to mast clamps are available but be sure that they are big enough to support a four element quad. The support should be 12" x 2" O.D. for the boom and 6" x 1½" O.D. for the mast. The clamp on your old antenna might do the job or order one from an antenna manufacturer.

The clamp must be capable of supporting both the 2" boom and the 1½" mast above and below the boom (Fig. 2).

About 50' of ½" galvanized guy wire, 2 heavy duty turnbuckles and 8 cable clamps are needed to give the boom additional support (Fig. 1).

Several companies offer all of these parts for under \$150 including the boom. This price can be cut if one makes any of the parts himself or has them on hand from other antenna projects.

There is no real difference between a quad shaped like a diamond and one shaped like a square. The important thing is the feedpoint (Fig. 1). Feeding the antenna at any point marked H results in horizontal polarization and feeding at any point marked V will result in vertical polarization.

The most widely used polarization is horizontal. It is easier to tune the antenna and the tower will have less effect on the antenna than if vertical polarization would have been used.

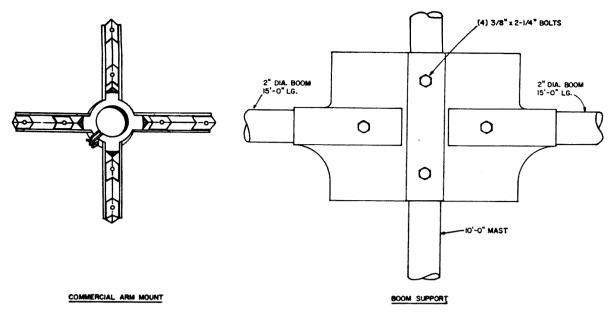

Fig. 2. The commercial arm mount and boom support used with the four element 20 meter quad. This particular design has withstood winds up to 80 miles per hour.

The diamond quad offers an excellent route for the feedline to be run. The feedline can be taped directly to the fiberglass arm with no ill effects. The square quad requires 4 insulators, one for each element (Fig. 1).

A quad is not an especially broad-banded antenna; the SWR can be tuned to almost 1 to 1 at any one frequency but the SWR rises more rapidly than does the SWR in many beams. This is not a serious drawback as the SWR is under 2 to 1 over most of the band (Fig. 3).

The resonant frequency can be changed easily by lengthening or shortening the wire or by using coils, shorted stubs, tuning stubs or other tuning methods.

The length of the wire on each side of the quad can be calculated by using the formula 248 or the formula 984 for the total length of each loop. The approximate total length of the wire for the 20 meter phone band is:

1st director	66'	6"
2nd director	68'	3"
driven element	70′	0"
reflector	71'	9"

The above lengths were calculated by increasing the driven element length 2½% for the reflector and by decreasing the directors 2½% from the driven element size.

The radiation resistance of the quad will be close to 50 ohms and the greatest gain

will be achieved when the elements are spaced:

1st to 2nd director 10' 6" director to driven 9' 3" driven to reflector 9' 9"

This uses all but 6" of the 30' boom.

- Select a flat place in the yard to lay out the quad arms. Mount the arms to the arm mount. Do this to each of the 4 mounts.
- 2. Drill ¹46 holes in the arms approximately 12′ 1″ from the center of the boom; drill a 2nd hole at 12′ 3″ in the bottom arm of the driven element. Be sure to drill all holes straight and in a level plane.

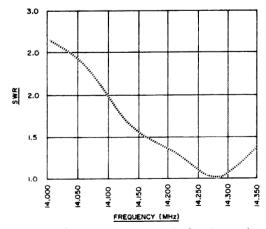

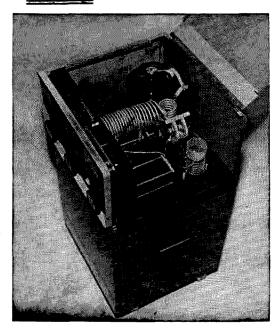

Fig. 3. Standing wave ratio of the four element quad. Although this unit was tuned for minimum SWR in the phone section of the band, even at the low end the SWR barely exceeds 2.5:1.

IT'S WHATS INSIDE THAT COUNTS!

Model LK-2000

Dimensions: 291/4" high 16" wide by 151/4" deep Shipping wt. 125 pounds

LINEAR AMPLIFIER

- ★ Easily handles maximum legal power for all modes with grounded grid, zero-bias linear operation.
- ★ Eimac 3-1000Z final provides full 1000 watts plate dissipation and longer tube life with exclusive after off cooling.
- ★ High reliability solid state power supply using computer grade capacitors for continuous duty.
- ★ A.L.C. output provides higher audio level without flat topping and the tuned cathode input provides higher efficiency with minimum distortion.
- ★ New tank design gives equal efficiency all bands with metered R.F. watts output to antenna or dummy load.

 $^{
m J}$ & $_{
m B}$ radio supply

Phone 213-769-7848 4837 Laurel Canyon Blvd. North Hollywood, Cal. 91607

- 3. Thread the wire, #14 enameled copper, through each hole, and on the last arm connect the 2 ends together and solder forming a closed loop; do this to each element.
- 4. Drill a ¼" hole about 1" from each end of the boom.
- 5. Attach a 10' x 1½" mast at its midpoint to the boom.
- 6. Drill ¼" hole about 2' down from the top of the mast parallel to the boom.
- 7. Slide the elements on the boom (a little grease or butter on the boom might help).
- 8. Attach feedline (52 or 72 ohm coax) to the driven element and run the coax along the quad arm and boom taping it with permanent black tape as you go.
- 9. Push 5' of the ¼" cable through the holes in the mast and attach the turn-buckles to each end of this wire. Cut the rest of the steel cable evenly and attach the wire to each end of the boom and to the other end of the turnbuckles (Fig. 1). Be sure that the turnbuckles are as wide as they will go before attaching the cable.
- 10. Raise the antenna to the top of the tower and drop it into place.
- 11. Tighten rotator bolts.
- 12. Tighten turnbuckles so that the boom is straight.
- 13. Run the feedline through the inside of the tower. Drive a 8' ground rod into the ground as near as possible to the base of the tower. Connect the outside braid of the feedline to the ground.

This quad has survived winds of 80 mph on a self-supporting tower 50' above the ground. If additional strength is desired a piece of wood or similar substance can be run through the boom to give additional horizontal support.

The gain of the antenna varies according to what method of measurement is used. Comparing this antenna's gain to what manufacturers claim their antennas get, this antenna exhibits a gain of about 12 dB. This gain was measured by using a S-meter in a communications receiver using a dipole 10 wavelengths away from the antenna.

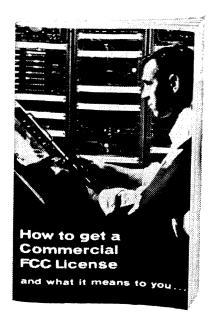

This is more than enough gain to work most stateside and DX stations using either high or low power.

Want a high-pay career in Electronics?

This free book may change your life

It tells how to go about getting the key to job success in the growing electronics boom—a Government FCC License

THERE'S A BIG BOOM IN ELECTRONICS. And YOU can be part of it. You don't need a college education or any previous experience in electronics. The free book shown here tells you how.

In the last 15 years, the electronics manufacturing industry alone has grown from \$2.7 billion to \$17 billion, and is expected to hit \$24 billion by 1970.

Thousands of trained men are urgently needed to help design, manufacture, inspect, test, install, operate, and service electronics marvels that are making headlines. If you qualify, it means a secure, steady high-pay job with a real future to it.

Maybe you'd like to become a broadcast engineer... put famous radio disc jockeys and television entertainers "on the air." Or be your own boss servicing some of the more than a million two-way mobile radio systems in taxis, trucks, trains, etc. Or work alongside famous scientists developing and testing such electronics miracles as picture-frame TV, desk-top computers, pea-sized hearing aids, rocket guidance and control systems.

Regardless of which you choose, the secret of "getting your foot in the door" is getting a Government FCC (Federal Communications Commission) License. It's government-certified *proof*, respected by employers everywhere, that you have passed a standard Federal exam on the fundamentals of electronics—that you're not just an electronics handyman, but a real "pro." Many jobs legally require it.

Now, because of the importance of getting your FCC License, Cleveland Institute of Electronics has prepared a valuable 24-page book telling you how to go about it.

ENROLL UNDER NEW G.I. BILL

All CIE courses are available under the new G.I. Bill. If you served on active duty since January 31, 1955, OR are in service now, check box in coupon for G.1. Bill information.

You will find out why the Commercial FCC License is often called the "passport to success." You'll see how and why the Government issues these licenses. You'll learn how you can get your license . . . and qualify for top opportunities in Electronics.

With this book, you will receive a second free book, "How To Succeed In Electronics." It's the catalog of the Cleveland Institute of Electronics . . . first organization to offer an FCC License Warranty. (CIE will refund all of your tuition if you don't pass the FCC exam . . . on your first try . . . after completing the course designed to prepare you for it.) You will learn why better than 9 out of 10 men with CIE training get their FCC Licenses, even though 2 out of 3 without this training fail.

To receive both books without cost or obligation, just mail the coupon below. If coupon has been removed, write to: Cleveland Institute of Electronics, 1776 East 17th Street, Dept. EL-1, Cleveland, Ohio 44114. Do it now—it may change your whole life.

Tilt that Quad at A Dollar A Foot

When the quad bug hit me three years ago, a basic fact of antenna design came into sharp focus. The delta-quad configuration I planned was comparatively new, and I had no doubt that there would be a long period of pruning and tuning. This called for a simple method of raising and lowering the antenna. Even if my calculations were accurate, I knew the antenna would have to go up and down dozens of times so that it could be adjusted for this particular location in order to correct for the individual conditions such as our unusually poor ground, the proximity of the carport, power lines, etc.

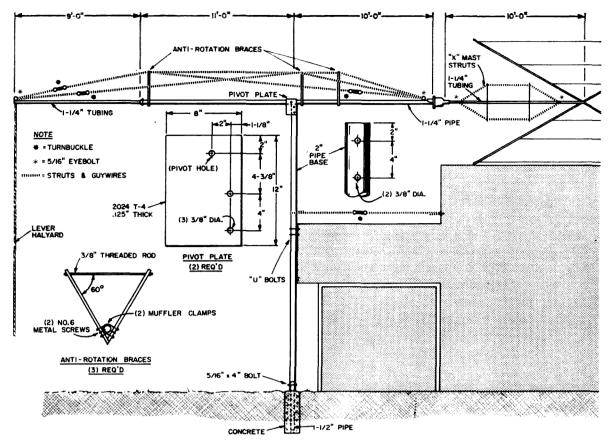

So before the antenna itself was touched, I concentrated on a "tower"-a somewhat generous term-that would permit quick, easy adjustment. Consideration was given to several of the sturdier crank-ups, tilt-overs. Had I been able to afford one of the more de-luxe commercial models, particularly those with power driven winches, there would have been no problem except that of adjusting, cutting, trying and re-adjusting at the 20' level. The cost of this equipment, however, went far beyond my classification or hobby expense, so I gave the question considerable thought and came up with the gadgetry shown in Fig. 1. It is ultra-simple, delightfully inexpensive, and completely effective for lightweight antennas.

Basically, the tower consists of two parts: a solidly set fulcrum at a reasonable height, a lightweight lever arm that would be able to take punishment. The whole works had to be high enough to raise the spider of the quad to a 41' height (half-wave on 20 M. for the bottom part of the quad square); had to be able to live with summer windstorms with gust velocities of at least 65 MPH.; and had to make the raising-lowering procedure a matter of minimum effort and time. I felt that it could be done at a low cost. It can.

There are two basic elements:

The fulcrum

A height of 21' seemed like a good fulcrum point for two reasons. First, it would allow the antenna to be lowered to the roof of the house at an angle that would allow me to make adjustments easily. Secondly, standard 2" black or galvanized pipe comes in such lengths, and with somewhat limited tools, I wanted to keep work to a minimum. I was fortunate in being able to buy from a local surplus metals dealer a piece of lightweight black pipe which has the same outside diameter (2.375"), but has a lighter wall (.121" vs. .154"). It is lighter in weight, easier to handle and drill, and is cheaper in price. To use this pipe as the fulcrum requires the drilling of two parallel %" holes at one end, 2" down from the end and 4" apart. (See Fig. 2). An anti-rotation bolt is added later. The fulcrum materials include, in addition to the pipe, two pieces of %th inch aluminum, 8" x 12" of a hard alloy such as 2024 T4 or harder. They are drilled with holes to match those on the pipe as shown. The additional %" hole higher and to the left of the mounting holes, is the actual pivot point. Machine bolts, %" x 4", hard-drawn and with lock washers are used to secure the two plates to the pipe. Mounting to the side of the house or carport is a matter of material available, personal choice, etc. A simple method is shown in Fig. 1. A 4' length of 1%" pipe was set in a chunk of concrete roughly 1' x 3' x 3' deep, with about a foot of the short pipe above ground, slightly offset from the facia boards of the carport. The base fulcrum is erected in as vertical position as possible by slipping the lower end over the stub in the concrete and tying the upper portion to the house facia in the most convenient and sturdy manner. Drill a 5/16" hole through both pieces of pipe and use a 5/16" x 4" hard-draw machine bolt to keep the 2" pipe from trying to rotate. Here I used two "U" bolts securely anchored

to the facia, plus a guy wire tightened with a turnbuckle to another facia board. For the base section, that's it!

The lever

The basic component of the lever is a 21' length of I%" black pipe with a %" hole drilled at a point 11' from one end for the pivot bolt. At right angles to this hole, two $\frac{1}{16}$ " holes are drilled, one 1" from the end of the 11' side, the second 7" from the 10' side. These are for the eye bolt used for the bracing cables, and the bolt used to attach the extension arm.

The last major piece of material is a 21' length of steel tubing with an OD of 1¼". I buy these in Phoenix from wire fence contractors for about \$3.25 per length. This tubing is amazingly resilient, and has been used for dozens of tough antenna chores. Cut off ten feet of this length, and set it aside for the top section of the whole works. The lower section is drilled at one end with a ¾6th" hole to match the anchor bolt, and with another ¾6th" hole about a foot from the end to match the hole in the I¼" pipe so that the pipe and tubing can be bolted into one unit.

Examination of the sketch of the lever will show that there is a heavy strain on it when it approaches the horizontal position. A pair of braces attached to the arm itself transfers this load to a 3/16th" bracing cable. I use two pieces of scrap aluminum channel, about ½" x ½" x 2'6" at each of the two brace points, secured to the pipe by "U" bolts. Really throw your weight into getting

Material List Approx.	Cost
1 length 2" pipe, black or galvanized 21' Fulcrum Base	\$11.00
l length 1¼" pipe, black or galvanized 21' Lever arm l length 1¼" steel tubing 21'	6.75
Lever extension and top mast	3.00
2024 T-4 or similar pivot plates	3.00
1 pc. 1½" galvanized pipe, 4' long	1.25
or similar for lever arm strut braces 4 pcs. aluminum channel, as above 4' long for cross-bracing top mast—if top mast	1.80
cross-bracing is used	4.80
15' additional if second facia tie is used Cable clamps, "U" bolts, eyes as needed for	.75
your own variations, plus turnbuckles 60' 4'" nylon cord if top mast cross	5.00

The above materials can be purchased at better than these prices in Phoenix from concerns dealing in surplus metals. And even at these prices, with a generous \$5.00 for miscellaneous small parts, you are over 40' at less than a dollar a foot . . . What is more important, you can really tune that antenna.

these on tight. A turnbuckle on the cable makes sure the arm is in proper tension, and basically, we have the lever. With your rotor mounted at this point, you are now slightly more than 31' above the ground.

Up to 41 Feet. Remember that 10' length of IX" tubing? For a light UHF beam, we've got it made. For a heavier antenna like the DeltaQuad used here, however, the weight (about 25 lbs.) plus the greater wind resistance made me spend a little more time and effort on that top 10' . . . I cross-braced twice along the length, using the same aluminum channel with two feet extending out on each side of the crosses formed. Since these were inside the quad itself, I used " nylon cord instead of steel cable. Its "stretch-shrink" cycle has had no apparent effect. The antenna bolts to the top of this braced mast. Center of the spider, 41 feet! The usual egg insulator-broken guy wires are attached to the AR-22 rotator here.

The only other item consists of a 20' length of cord, strong wire or cable which is connected to the bottom of the lever arm. When the antenna is lowered, this halvard hangs down to the ground and is pulled until you can grasp the bottom of the lever itself.

Assembly

Erect the fulcrum post as shown making sure that it is vertical. Raise the lever arm. complete except for antenna, to the roof. It may take a little help to thread the lever arm into the pivot slot, but I do the job myself with an inexpensive block-and-tackle on the top of a very makeshift gin-pole. It takes a ladder to get to the pivot point, and without the gin-pole, getting the \(\mathbb{Y}'' \) x 4" pivot bolt can be something of a chore, but with a little push-pull help from a man on the roof, the job can be accomplished in a few minutes. You should be sure as you do this that the halyard at the bottom end of the lever is loose and falling to the ground. Attach your preliminary guys to the rotator, attach the antenna and its coax, and you are set.

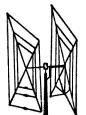

The amount of pressure required to raise the antenna depends on its weight and how closely you have stayed with these materials. For this installation, a 23 lb. bucket of sand exactly balances the weight of the whole upper lever complex: next chance I get to pick up a chunk of lead, etc., I'll cut that down.

Raising and lowering

At this QTH, the antenna is attached to the carport on the west side of the house. To lower it, I rotate the quad to the east or to the west, depending on which element I want to work on. I then detach the rotor guy on the west side, release the simple lock that holds the lever to the fulcrum arm and raise the lever so that the antenna starts down. The lever is slowly raised, finally goes to the point that the lever cord is used for the final distance as the antenna comes down to the roof. Outside of antenna rotation. total elapsed time, 10 seconds. After completing the adjustment, the lever cord is pulled and the process reversed. Maybe 15 seconds. Energy expenditure,—little.

On the basis of material costs in Phoenix, we are talking about a total figure for the entire gadget, less guys of about \$40.00. The "Tower" has been up for over two years in various sizes and variations. It has taken a lot of punishment from the wind. And most important, it has enabled me to have the antenna easily available for every possible change with the greatest of ease. 1 think it is a first class investment.

An Easy-to-Erect Quad

If you want the best antenna for DX, and the one which is easiest for the home constructor to erect; then the antenna for you is the cubical quad.

Now, the first statement is easily confirmed. It is only necessary to sit on the fence and hear what all of the big (and usually rare), DX stations use. I find personally that at least 60% of all European stations use quad antennas.

The second statement is usually not so easily proven. If you have ever struggled up a tower with a twenty-meter beam on your shoulder, or almost slipped a disc when your cubical quad got caught in the stay wires at the thirty-foot level, then I am sure that you agree. There is one way

out here, and that is to erect the antenna in two parts, the driven elements and boom in one part, and the reflector assembly comprising the rest.

Fig. 1 shows the boom and driven element section before erection. Ready-made quad parts are not easily available in this country, so we had to start from scratch. We made the boom from 2"OD galvanized water pipe. A %" mild steel plate 6" square is welded to each end of this pipe. One plate has four ¼" holes drilled as shown in the photo, the other end plate has four radial supports welded in place at an angle of approximately 20 degrees to the plate. The third plate has four ¾" holes drilled in exactly the same positions as in the first

Fig. 1. Boom and driven element section before erection.

Fig. 2. VK5DS holding the driven element section of the quad.

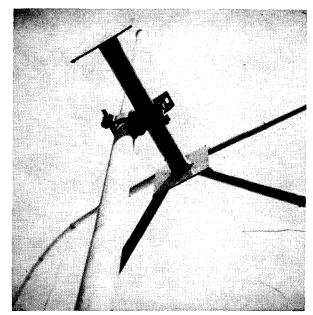

Fig. 3. The boom is attached to the mast with a builder's scaffold clip.

plate as well as the other four radial supports, which are welded, also at 20 degrees.

These eight radial supports are made from galvanized 1" OD steel tubing, each being two feet long. The radials themselves can be made of anything. We used Australian oak, (a long-grained timber), and finished them with marine paint. Fiberglas fishing rods would be better, if available. Whatever material is chosen, the radials need to be about 13' long.

Element lengths can be found in Bill Orr's Quad Antenna Book, and it is strongly suggested that the wires be laid out on the ground and individual lengths marked off so that they remain symmetrical when wound onto the radials.

Erection, as mentioned earlier, is very simple. It is quite easy to handle the individual parts of the antenna, as VK5DS demonstrates with the driven elements in the accompanying photograph. (Fig. 2)

The tower at VK5VB is a 60' Homelite; we climbed to the top and hauled the driven elements up on the end of a piece of rope, which was tied around the boom. The boom was attached to the rotator (2"OD pipe), with a builder's scaffold clip (Fig. 3). We have found these fittings a most convenient way out of the problem of fastening which everyone seems to have with antennas which are too heavy to use TV fastenings.

The other elements are then hauled up the tower and fastened to the boom-plate with four ¼" bolts. (Fig. 4)

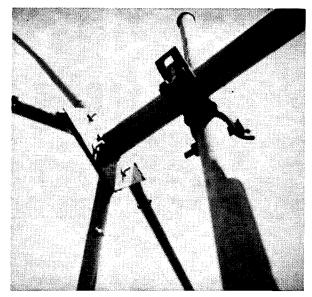

Fig. 4. The other elements of the quad are raised with a rope and fastened to the steel plate on the opposite end of the boom from the driven elements.

If a crank-up tower is used it becomes that much simpler to mount the thing. You can then climb up a stepladder with the antenna sections one at a time and it becomes a one man operation.

We drive each section of the antenna separately with 72 ohm coax and the radiation resistance is correct on all bands up to 50 MHz. This of course is largely because the correct ratio of reflector/driven element spacing has been maintained on all bands.

The finished job, whilst not aesthetically appealing to my wife, I think looks pretty good (Fig. 5).

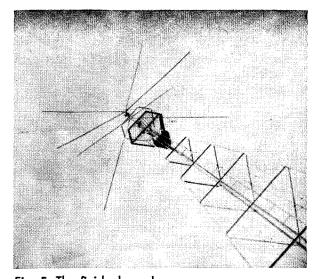

Fig. 5. The finished quad.

Bibliography of the Cubical Quad

Since the first published description of the cubical quad by W1DF in QST for November 1948, there has been a veritable flood of quad articles published in the amateur magazines. W1DF noted in his article that the quad apparently originated HCJB in Ecuador; from this rather obscure beginning the quad has grown into one of the most popular amateur antennas. There are two element quads, three element quads, four element quads, quad kits and quad packages-with sizes and prices to fit nearly anyone's space and pocket book. The following is a comprehensive list of cubical guad articles that have appeared in the ham magazines since WIDF's original description back in 1948.

of the world-famous RADIO HANDBOOK

- Most comprehensive how-to-build-it source
- Problem-soiver for designers & builders

Completely revised and enlarged by William I. Orr, W6SAI. This is the comprehensive communications manual which is the industry standard for electronics engineers, technicans, and advanced radio amateurs. Explains in authoritative detail how to design and build all types of radio communications equipment.

LATEST HOW-TO-BUILD DATA

The new 17th Edition of the RADIO HANDBOOK presents design data on the latest amplifiers, transmitters, receivers, and transceivers. Includes greatly enlarged sections on single-sideband equipment and design, and semiconductors. Gives extended coverage to r-f amplifiers, special vacuum-tube circuits, and computers. All equipment described is of modern design, free of TVI-producing problems.

THOROUGHLY REVISED & UPDATED

Provides a complete understanding of the theory and construction of all modern circuitry, semiconductors, antennas, power supplies; full data on workshop practice, test equipment, radio math and calculations. Includes aspects of the industrial and military electronics fields of special interest to the engineer and advanced amateur. The 17th Edition of the RADIO HANDBOOK provides the broadest coverage in the field—complete information on building and operating a comprehensive variety of highperformance equipment. All data is clearly indexed. 832 pages; $6\frac{1}{2} \times 9\frac{1}{2}$, hardbound. Invaluable for amateurs. electronics engineers. and designers.

Simple Bias Supply

Possibly the reason that many amateurs do not use protective bias in their transmitters is that bias supplies are usually expensive and hard to locate. There are very few transformers that are suitable for bias supply use on the surplus market and new ones are costly. A very simple supply can be made from the heater supply of the transmitter. The circuit shown is a half-wave tripler operating from the 6.3 volt heater line. SR1, SR2, and SR3 are low voltage silicon rectifiers. Usually the filtering is adequate at point X. If more filtering is desired, R2 and C4 can be added. The output should be between 20 and 30 volts. If a higher voltage is desired, taking the ac off a 10 or 12 volt winding, if one is available, will raise the voltage to approximately

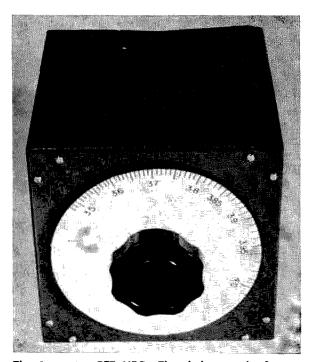

50 volts. Other uses for this supply include: bias for linears, bias for class AB1 and AB2 modulators, power for transistorized stages, etc. The supply can be used to deliver quite a bit of current, probably a few hundred milliamperes. It has good regulation and can be used for bias in stages where grid current is drawn, such as class B modulators, etc. The total cost for the supply should not exceed \$3 or \$4, and can be built for considerably less if some of the parts are in the junkbox.

An FET VFO for 80 Meters

One of the big advantages of the field effect transistor oscillator is that it does not appreciably load down the tuned circuit. If you take a very close look at the circuit Q versus frequency stability curve you'll find that highly stable oscillators are coincident with high Q tanks. With the relatively low impedances encountered with the bipolar transistor', circuit loading is a severe problem which seriously affects frequency stability. In addition, the element capacitance of the bipolar device is very

The 80 meter FET VFO. The dial is made from a National AVD-250 planetary drive; the scale is printed on a paper disc which is glued to a 4 inch aluminum disc. The drive mechanism is on the rear of the panel; the aluminum disc is attached by means of screws and 1/4 inch spacers.

complex, varying with voltage, temperature and current. It is difficult to predict exactly what a given device will do because the rate of change of capacitance is a function of the bias level, and varies from device to device. On the other hand, the capacitance of the FET is almost completely unaffected by the source current, and the factors that influence FET capacitances always increase with temperature. Since the properly designed FET oscillator always has a positive temperature coefficient it is relatively easy to compensate.

The complex capacitance of the bipolar device has both negative and positive temperature coefficients, and for wide excursions in temperature, bipolar transistor oscillators are very difficult to compensate. Never the less, transistors inherently generate very little heat, and in amateur applications this difficulty is often not apparent. I can remember spending three weeks of continuous labor trying to compensate a 3 MHz oscillator that was to be used on one of our space vehicles; the transistors finally had to be changed before a stable unit was obtained.

An example of the frequency variance with temperature of two oscillators, one with an FET and one with a 2N918 bipolar transistor is shown in Fig. 1. Note that whereas

1. The bipolar transistor refers to conventional junction transistors made up of P-N junctions at the emitter, base and collector. In these transistors the current through the junction consists of both electrons and holes (absence of electrons). Because there are two types of current carriers (electrons and holes), these devices are referred to as "bipolar". On the other hand, the field effect transistor is a "unipolar" device because the current carriers are either electrons or holes, depending on whether it is an N- or P-channel device.

the frequency of the FET circuit decreases in a somewhat linear manner, the frequency of the bipolar oscillator first increases and then decreases. The negative temperature coefficient of capacitance dominates when the frequency increases and the positive coefficient as the frequency decreases. This type of curve obviously can not be compensated with a temperature sensitive capacitor in the tank circuit. It is also apparent from this graph that the bipolar circuit has a larger drift in frequency for a given change in temperature over most of the range. In many cases the ham oscillator is operated within the temperature range at the crest of the frequency curve where these undesired effects go unnoticed.

In the VFO described in this article. FET's are used in the oscillator and buffer stages and a bipolar transistor is used in the power output stage. The oscillator itself is a conventional series-tuned Colpitts or Clapp circuit with large silver mica capacitors providing the necessary feedback. The large value of these capacitors tends to swamp out any changes of capacitance within the device itself. The frequency drift of this unit was so small (probably because it was operated at room temperature near no vacuum tube heat generators) that no temperature compensation was required. most cases no compensation should be necessary, but if thermal drift is a problem, a negative temperature coefficient capacitor may be added in parallel with the 50 pF tuning capacitor as shown by the dotted lines in Fig. 2. In the event this compensating capacitor is required, the 75 pF capacitor should be reduced by a like amount.

Since a compact unit was desired, toroidal coils were used to maintain high Q without massive air wound inductors. Since there is virtually no field around a toroidal inductor, they may be placed near other objects in the circuit without affecting their Q. Sometimes this low amount of external field can be a problem because it's difficult to couple a grid dipper to the circuit to find out its resonant frequency. In addition, toroids are quite susceptible to 60 hertz ham pickup, and this is accentuated by the high impedance FET, so care must be taken to shield the circuit properly. In the author's case the hum was completely eliminated when the circuitry was mounted in a metal box.

To reduce loading on the oscillator stage, an FET source follower is used as an un-

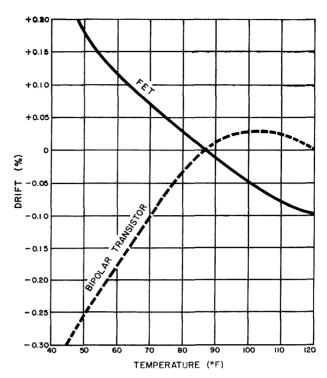

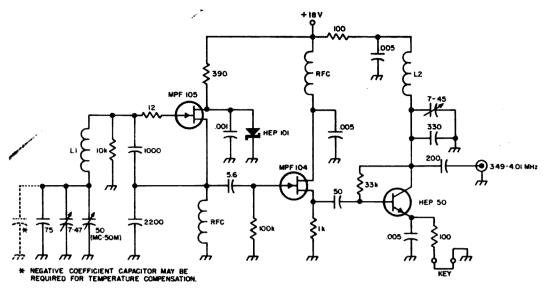

Fig. 1. Typical drift characteristics of FET and bipolar oscillators. This graph is based on a starting point of 30° C (86° F) and shows that the bipolar transistor has both negative and positive temperature characteristics while the FET capacitance has a positive temperature coefficient (causing the frequency to go down).

tuned buffer stage. The low value of coupling capacitance, 5.6 pF, serves to further reduce the loading on the oscillator. To eliminate any possiblie pulling or resonance effects, no tuned circuit is used in the buffer stage. The stage shown in the schematic exhibits extremely high input impedance and is a very effective isolator; when the output stage is keyed, there is no perceptible change in the rf voltage across the oscillator tank and the frequency remains rock stable.

The stability of the supply voltage to the osicllator is maintained by the 400 milliwatt, 9 volt zener diode (HEP 101) across the drain to ground. With the circuit constants shown, the voltage on the drain of the MPF 105 field effect transistor remains within 1% of the Zener voltage as the supply voltage varies from 13 to 25 volts.

The output stage uses a low cost silicon transistor in a conventional class C rf power amplifier circuit. At 4 MHz this stage has about 25 dB gain and provides 2.0 volts RMS output; this is more than sufficient to drive most transmitters. If the second harmonic at 7 MHz is desired, it is recommended that another HEP 50 stage be added

LI 53 TURNS NO. 28 ON 0.68" TOROID (AMI-TRON T-68-2) L2 27 TURNS NO 26 ON 0.68" TOROID (AMI-TRON T-68-2)

Fig. 2. The RFC's used in the FET 80 meter VFO are miniature 1 mH units available from J. W. Miller. The oscillator and output stage as shown here will run continuously. To key the output, remove the jumper marked "key" and connect the two terminals to your key. The two toroids are available postpaid anywhere in the U.S.A. for \$1.00 from Ami-Tron Associates, 12033 Otsego Street, North Hollywood, California 91607.

as a doubler. In the original model of this VFO the final stage was operated straight through on 80 meters and as a doubler for the higher bands. Although there was sufficient drive on 40 meters, there was not enough output on 20, 15 and 10. In fact, at the higher frequencies, the transmitter operated at the resonant frequency of the

Interior of the 80 meter VFO. The FET oscillator and buffer are in front of the shield, the HEP 50 output stage to the rear. The planetary drive is attached to the front panel with spacers. The screws and spacers which hold the dial pass through a 11/4 inch hole in the panel.

doubler tank (or its harmonic) and refused to be varied by the FET oscillator!

In this VFO all the components were mounted on a 1/8 inch sheet of micarta 31/2 inches wide and 5½ inches long. Soldering terminals were provided by drilling holes in the micarta with a number 42 drill and installing Vector pins (Vector T9.4). This meth d is very rigid mechanically and is easy to duplicate. A narrow strip of thin copper was mounted in the center of the micarta terminal board to provide a common ground for the circuitry. At the front of the board a Hammarlund MC-50M variable capacitor was mounted with the copper strip between it and the board. Except for the toroids, all the components were mounted by simply soldering them to the Vector terminals. By placing the body of the component next to the board and by using short leads, almost all vibration and its effects were eliminated. In fact, the completed unit can be slammed down on the bench with no perceptible change in frequency.

When winding the toroids, the turns should be spaced to completely fill up the circumference of the core. In this way maximum Q is obtained. After the toroids are wound, a little polystyrene Q-dope will hold the turns in place. The completed toroids are mounted to the board with $\frac{3}{16}$ inch flat head nylon screws that came in a nylon

screw assortment from the local hardware emporium. If you can't find any nylon screws, brass screws and fiber washers will work as well.

The frequency of the oscillator is set to the proper range with the 47 pF trimmer capacitor. With the variable capacitor plates fully meshed, set the oscillator frequency to about 3480 kHz with the trimmer; when the variable is fully open, the output frequency should be approximately 4020 kHz. If a full 500 kHz range cannot be obtained, decrease the value of the 75 pF shunting capacitor to the next lowest value (68 pF) and try it again. If you want to reduce the frequency coverage, increase the value of the 75 pF capacitor. The power output stage is adjusted for maximum output at 3750 kHz.

Although this unit was designed specifically for 80 meters, it may be used on other frequency ranges by simply changing the

number of turns on the toroid coils. Remember that the center frequency of the desired range is set with the inductance; the frequency spread is controlled by the size of the 75 pF shunting capacitor. In some cases a little juggling back and forth between the capacitor and inductor may be required to get the desired results, but it is not difficult nor time consuming.

Conventional bipolar transistors have eliminated many of the problems in stable VFO design, but they still have several minor disadvantages. The field effect transistor virtually eliminates these disadvantages and combines the low power and low heat of the bipolar device with the high impedance and predictable element capacitance characteristics of the vacuum tube. This VFO has provided such extremely stable results on 80 meters that an 8 MHz unit is under construction for use on six and two.

... W1DTY

Thermistors

We normally think of the lowly resistor as just that and only a load for a tube or transistor, a voltage dividing device, or a voltage dropping device. Modern science has provided to us with several exotic gadgets in the form of resistors with very special characteristics.

The most common of these is the temperature dependent resistor, better known as the thermistor. One of the most prevalent uses for the thermistor is in the audio circuits of the transistor radio where it limits the current as the temperature rises and thus prevents thermal run away. Many of them are used in ultra sensitive thermometers operating over a very narrow range. They can be made so small that in laboratories they are imbedded under the skin of animals to keep a constant check on body temperature. Others have been used to check wind velocity. Here two are used. A small voltage is applied to both so that they heat up. One is placed in the wind stream and the other is protected from the wind. Of course the one in the wind will cool down just as you cool your coffee by blowing on it. Measuring the current difference from one to the other will tell how hard the wind blows.

Another type, not as well known, is voltage dependent resistor or varistor. These

also come in many sizes and shapes. The TV repair boys have run into these where they are used for stabilizing the line deflection against voltage fluctuations, tube ageing, etc. They are also necessary in automatic synchronization circuits.

Varistors are used in great quantities for spark suppression and contact protection where the resistor acts to reduce voltage build-up and subsequent sparking across relay contacts.

Another use of varistors is voltage control. They cannot do the job of the fancy tube type or zener diodes but for the size and price they do give a high degree of stabilization.

Still another special resistor is the light dependent resistor. Actually this is a type of photo cell, one that does not generate electricity when exposed to light but only changes its resistance. These cells are usually made with a layer of compressed and sintered cadmium sulfide. Their resistance will range from 100 ohms in strong light to 100,000,000 in total darkness. The spectral sensitivity is fantastic, ranging from visable light to a good way into the infrared range. The peak sensitivity is at 6800 angstrom which is the center of the visable red.

Tube Symptom Troubleshooting

Here are some useful hints to help you fix your inoperative gear.

Troubleshooting procedures in volving tubes naturally cover equipment involved in any ham interest, including ATV. This article contains a general accumulation of suggestions based on experience I have had in repairing electronic equipment under pressure which invariably leads to work routines that cut away as much lost motion as possible. Whether you are in a hurry to repair something or not, however, any clues furnished by faulty equipment which you correctly interpret and therefore avoid following false leads makes you a better troubleshooter. I know you probably check tubes early in the routine but how do you check them? Are you getting the most out of each observation, each test, each substitution? Any check you make 'just to see what happens' is aimless and although it will probably get the equipment fixed it isn't likely to contribute new information to make it easier the next time. Here are some clew furnished by tubes you may not be aware of:

1. Gassy Tube: The blue glow is not necessarily bad. If it wanders around aimlessly in the envelope like in a smoke-filled room, that's bad. Small, bright patches of blue are normal. They are also useful troubleshooting guides since they indicate a functioning tube that is being driven. For example, observe the action of an audio power output tube or a horizontal sweep output tube with an without drive. Watch these blue patches ignite with the tube operating and go out when the tube is disabled or drive removed.

2. Nosiy tube. You tap or rock the tube and the speaker emits noise. So you pull the tube, put in a new one, and the noise stops so the old tube was no good. Not necessarily. Pulling out the old and pushing in the new probably cleaned the dirty socket contacts. Put the old one back in just for the heck of it—you probably don't really need the new one and you have saved face and money.

3. Microphonic tube. Two causes for this

but one is an unnatural cause; rapping on the tube envelop to "check" it. Quit doing that. My experience includes a stereo system that was checked for every conceivable thing because of low frequency distortion and it was only a howling 12AX7. Moral here is, automatically blame tubes for everything because they are often to blame and the're easier to get to. I think it possible for new tubes and very old ones to be equally suspect. Manufacturers believe that a tube that survives the 90 day warranty will have a long life. Tension of grid wires causes the frame-grid tube to be prime microphonic candidate.

4. Red plates do not necessarily mean the tube is ruined or at fault. You are familiar with the usual maladjustments that cause excess plate dissipation in a transmitter. Are you familiar with the series B+ circuit? If an overload occurs in the low B+, the audio output tube is overworked and turns red: but the fault is not in the tube and seldom damages it. A tv horizontal output tube turns red if drive is lost so check the horizontal oscillator. In a color set, the high-voltage regulator tube fails. These are all examples of a fault indicated by one tube but caused by another tube or component.

5. Tube shields. You do replace all tube shields don't you? Are you sure that they are well seated and grounded. A good way to inject a signal into a tube is to connect the signal to the tube shield and then pull the shield up so that it doesn't touch ground. Using the same reasoning, an ungrounded shield can cause more grief than a missing shield. Manufacturer's got so tired of missing shields that they developed one that won't come off. The top portion is turned counterclockwise and pushed down. Hopefully, the top portion is pulled up and locked in place after service is rendered. If adding a shield cures a problem, be suspicious. Here is an example: By adding a shield in a ratio detector circuit, sound distortion was eliminated. However, the shield really added a reactance that should have been added by adjusting the sound transformer. Of course, we are speaking of manufactured and proven equipment in this instance—not experimental work.

- 6. Filament dead so tube is dead because putting in a new tube cured it. Also, maybe not so. If the tube has a base, crimp the filament pins with a sidecutter. Hardworking tubes like the 5U4 get pretty hot and the solder can granulate. Then again, it may not have been soldered well in manufacture and electrolysis has finally insulated the connection. Try it—what have you got to lose? By the wey, if the tube socket pins get that hot, better resolder them, too.
- 7. Clever trick. Look into glass envelopes now and then and try to interpret abnormal indications. Suppose a technician sees the 6V6 screen glowing and correctly surmises that the audio output transformer is open, causing the screen to dissipate far above normal. Didn't need a meter, a speaker, bench work, substitute tubes, etc., to solve that one.
- 8. Cracked envelope. You should always perform a visual inspection of tubes before pulling them lest you cut yourself on cracked glass. A cracked envelope will often show a white flare somewhere on the glass. Even if you don't cut yourself, it's a nusiance to pick bits of glass out of the socket well. Might be a good idea to buy one of the inexpensive tube pullers and save your fingers.
- 9. Heater cathode leakage. A television provides more clues than a radio. It causes 60-hertz hum or one black bar or the pix tube. The filter problem (120-hertz hum) causes two black bars. If the hum gets into the sweep circuits instead of the video, check for leakage in deflection tubes and the pix tube will provide evidence in the form of picture bending or poor color convergence. (This stuff goes on. We've got to try and make this brief but a book could be written on the things a tube will tell you). The intensitity of the hum in the audio channel provides a clue because the closer the defective tube is to the antenna the more amplification the hum receives. When you build equipment, take the precautions given you by the tube manufacturer concerning tube orientation since this often relates to the plane of the filament.
 - 10. Mystery tubes. If you can't read the

tube type on the glass envelope, breathe on it as you would when cleaning your spectacles. If this doesn't work, put the tube in the refrigerator ice compartment. Often, frost will form in a manner that will outline the disappearing legend. The interior of the tube is frequently distinctive enough to determine the type. The 6AV6 and 6AL5 are easy ones.

- 11. Suffix letter A. The letter "A" following tube type often means the manufacturer has improved a tube; sometimes because the original was a stinker. Sometimes because of a specific change such as delayed warm-up characteristics. Two examples are: the 6U8 and 6U8A and the 6AQ5 and 6AQ5A.
- 12. Tubes are not spark plugs. Don't put in a round of new ones at regular intervals to give the set that "old zing". Too many circuits still detune and must be adjusted after tube replacement in wholesale lots. Anyway, that's guess work.
- 13. The best tube tester is a new tube. If you want to see filaments go and microphonics develop, take out all the tubes and brown-bag'em to the tube tester and back again. Dynamic testing of a tube is worthwhile. The short test is a ghastly thing. Some people hammer the daylights out of the poor tube and I don't know if they are vehemently trying to prove or disprove that a short circuit exists. A good gadget is a soft rubber ball mounted on a dowel rod. Tap the tube gently with it or tap the chassis near the tube (a little harder) with the same tool.
- 14. Tube substitutes. Let's be suspicious except in emergencies. Unless your vessel is marooned and Captian Video asks you to raise the space rangers, it is better to get the original type but hardly ever necessary to specify the original manufacturer of the equipment. You should use the same type if a tube manufacturer has his name on it to avoid the thing called divided responsibility. For example, a GE serviceman is reluctant to replace an inwarrantly RCA tube without charge and you are not prepared to take warranty tubes to two or more places if they should fail. An example of tubes that are erroneously listed as substitutes are: 6BC8, 6BQ7A, and 6BK7. Get the original type since interchanging these can bring you an alignment job. At the other extreme, I once used a 6K6 to temporarily substitute for a 6X5: had to chop

off unused pins and the control grid performed well as one of the rectifier plates. It was an emergency. A 6AV6 will always substitute for a 6AT6 if you want a little more sound.

15. Tube plate caps. Easy does it! Don't make extra work for yourself. Take the connector off very carefully. It will take you about one hour of cross-eyed work to replace the socket on a picture tube if you pull the plug off too quickly. But you should pull these things off and make sure there is continuity. The hot plate cap of a transmitting tube, highpower PA tube, horizontal deflection tube, etc., often renders the solder joint useless. Sometimes, the connection works but high-voltage causes a constant arc that continues to deteriorate the joint and produces hard-to-trace interfering signals. If the heat has also hardened the lead, perhaps you should replace both the cap and the lead.

16. Tube swapping. Good idea if the tubes are of the same type. A transmitter may have two or three tubes of the same type for low level audio, speech amplifier. vox amplifier, etc. By swapping tubes you can probably trace your problem by generating a new one. There are limits to this and fringe benefits, too. If a tube is marginal and operating in a critical circuit, swap it with a like tube in a circuit which is less critical. Often this will not only disclose the trouble but allow you to use the marginal tube a little longer. Tubes in the microphone amplifier stage may be slightly microphonic or low gain but work well in a higher level stage. When troubleshooting television, swap sweep circuit tubes to track down problems but don't get carried away in rf and video circuits.

17. Filament continuity. The rule of thumb is this: If the tube has seven pins, check between pins 3 and 4. If nine pins, check between 4 and 5 and 9. All do not use pin 9 (such as 6BQ7A) but 4 and 5 are always used. For octal sockets, usually pins 2 and 7. Rectifiers (like 5U4) are pins 2 and 8. If 2 and 7 don't work, check 7 and 8 (like 6SI7).

18. Tube reinsertion. Before you pull a keyless tube from a socket that is obviously hard to reach or see, remember the trouble you had the last time trying to get it back in. The simple way is to remove the tube without allowing it to rotate in the hand until you get it into the light. Then, remem-

ber its orientation with respect to the chassis. Someday, when you have the chassis out, do this: Take a narrow strip of masking tape and stick it to the side of the tube and allow it to extend down and attach to the shield socket and then cut it at the top of the shield socket. Your sense of feel will tell you when the edges of the cut ends are aligned for subsequent replacement. Of course, you can often see the socket shield but not down into the socket: in this case the tape works very well.

Big bonus hint: Once upon a time, the tube manufacturers built a clever tube box for any kind of little tube but they didn't tell anyone how to use it. I suggest a game. Give a boxed tube to a friend and ask him to remove the tube. He will either open one end and pick away at it to get the tube out, or he will open both ends and push the tube out. Either way is illegal. If you'll look in the box, you'll see two cardboard wedges anchored at the box corners. If you invert the box over your hand and push at these corners of the box (using thumb and forefinger, naturally) where the wedges are attached, the wedges will expand and allow the tube to fall into your hand. It's a little thing but it looks so, well-professionalyou know what I mean?

The ATV ham shouldn't use the family tv for a monitor. Especially, for video input, it's necessary to add a switch and jack to "jeep" the instrument which will void the warranty. It isn't a question of whether the serviceman likes it or not since you obviously fix your own tv—don't you? I could give you a list of televisions that can't be "jeeped" anyway: especially color sets. The alternative is to get an old dog from the tv shop or garage sale and fix it up; also applying the suggestions on tube troubleshooting I've given you plus these hints particularly applicable to tv.

Don't fuss with tubes and replace the tube rectifier with diodes to get enough width and then discover the yoke isn't pushed all the way forward. Adjust the ion trap (if any) for brightest raster with the brightness control at maximum. Do not use the ion trap to get rid of neck shadows at the expense of brightness. Use the centering adjustments for that. You may be surprised to find B+ in an old set too high instead of too low. This can happen if a number of original tubes are still in use since they have all declined and the total current drain is less

than the "no life" value. If you aggrevate this situation by putting in diodes for rectifiers, expect some other breakdowns such as electrolytics. Don't borrow trouble. When you get a used tv, inspect the kinescope faceplate for deep scratches which are a dangerous invitation to implosion. Especially since I'm afraid you're going to let it run in the shack without its cabinet—a bad practice. When you get the television running for the first time, the picture may indicate poor emission. It might be caused by a long period of idleness so put on the picture tube brightener and then take it off again after a while—don't use it if you don't have to

More on the tv which has sat idle a long while. The electrolytics can be reformed first and possible failures can be avoided. To do this, apply the line voltage through a Variac for while with the B+ output disconnected from the load and input not too low to endanger the power transformer. This suggestion is for us cheapskates. Others prefer to apply higher than normal voltage and blow what's going to blow—tch! tch! If you need a replacement picture tube, investigate the possibility of a substitute at lower cost. The years following manufacturer of your set finds new types and the

cost of types fluctuating up and down according to the number manufactured. The majority of instruments use the "21 inch" tube with the portable sizes following close behind and the sizes above 21 inch being the poorest investment.

Look out for those dangerous metal picture tubes since they bite everywhere. They don't kill you but you break your neck jumping out of the way. If you get corona from these, it will usually be around the bell (forward of the yoke). To cure this, take the picture tube out and wash it thoroughly with soap and water, dry, and apply a good wax all around the bell. When you wash glass envelopes, be careful with the acquadag coating which forms one condenser plate for high voltage.

Lastly, don't improve the tv with changes in tube types for better signal-to-noise and such unless you got a good plan; like the lone ranger. It's usually easier to preamplify outboard and the 432-MHz converter can use the preamplifier as its if amplifier.

You know, I think the most embarassing thing of all is to get deep into chassis troubleshooting and then discover a tube under there—yech!

. . . WAØNEA

Faraday Shields

A simple device that for some reason has fallen into oblivion is the Faraday screen or shield. It is still important enough to the FCC that it is included in the Tech and General class license exam.

All of you, I am sure, know that a Faraday screen looks like a big comb with one common wire with a lot of other wires running out from it and not connected on the other end.

The Faraday shield eliminates capacitive coupling between coils. The desired signal should be inductively coupled because this is tuned to the desired frequency, be it the antenna or another coil. The capacitive coupling does not see anything except a mass of metal and any frequency present can be transferred. This can cause all kinds of stray stuff to show up on the feed lines and especially some of the harmonics and even some of the subharmonics in the case of a transmitter with multiplier stages. All

of these things can cause or add to the TVI problem.

The Faraday screen prevents the electric field from one coil reaching the other, but has no effect on the magnetic field. This is because of the open-ended wires. No current can flow in an open wire and current must flow to give effective magnetic shielding with non-magnetic material.

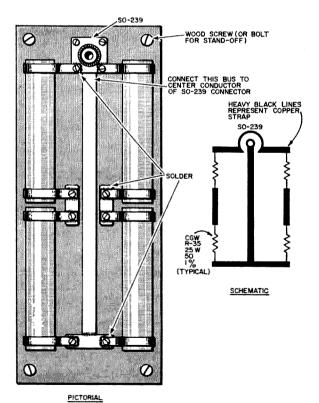

Faraday screens can be made quite easy and if you have harmonic troubles, and don't know what to do next, why don't you try one? The screen should be a bit longer than the coils to be coupled. Wire size? No. 18 is about the largest that should be used. Space the wires about the same as the diameter of the wire. One good way to make one would be to glue a bunch of wires to a thin piece of plastic. This would give excellent support and a couple of brackets would make an easy job of mounting. If you have a printed board making kit, it would be simple to draw a bunch of lines with the etch stop pen, then etch away the copper between the lines.

A \$2 200-Watt Dummy Load

Stop creating QRM. Test into an inexpensive dummy load.

Everybody tells the radio amateur, "You ought to feed all of your test transmissions into a dummy antenna, and not radiate needless interference." For a starter does he go out and buy a Bird Electronics 1,000 watt rf watt meter, Model 694 for only \$365.00? Works very nicely throughout the 2-30 MHz range, according to the spec's. Or maybe the Waters dummy load for \$135—a very nice item—wish I had one. Or perhaps the Heathkit Cantenna for only 10 bucks, plus postage and four quarts of oil. All of the above items are certainly reasonably priced, according to one's needs; but

Details of the Meshna-special dummy load. The resistors are 35¢ apiece. The board is 4 x 10", and preferably fiber glass or bakelite. The resistors are supported by $\frac{1}{2}$ " or longer spacers.

what do you say to the ham with 150 or 200 watts input and only a couple of bucks to spare? Cheer up, help is on the way . . . "Noninductive, late style 50 ohm, 25 watt resistors, 35c," said the ad. So I bought four of these from Meshna . . . four of these in series-parallel connection should give 50 ohms effective resistance, with 100 watts of heat dissipating ability. Anyone can see from our most elementary drawing that you don't need to be an electronic genius to duplicate this very simple item. The only additional cost was for an Amphenol type SO-239 fitting and the surplus Fiberglass board on which the whole assembly is mounted. If you feel really "sharp" you might choose to run the center conductor in the form of a three-wire bus, or maybe a copper strip. This is supposed to cut down on "stray inductance" and make the dummy load resistance closer to 100% non-reactive. I checked out the final product on a Heathkit DX-100 transmitter and found that the SWR was fairly low on 40 meters, reading 1.05 to 1 on a Knight SWR Meter. This rose to 1.2 to 1 on the 21-MHz band. Maybe the resistors are non-inductive at 2 or 3 MHz, but they seem to become more reactive as the frequency increases. But for two bucks, you can't ask for perfection, can you?

Maybe not, but you can try. I swiped a few feet of the wife's Reynolds-Wrap from the kitchen. I made up some experimental coils from the aluminum strip, approximately 1 inch wide, and shaped the coils to resemble the resistors. With the trusty griddip oscillator, they resonated close to 68 MHz when shunted with a presision 100 pF. condenser. The coil was connected directly to the capacitor terminals—this comes too close to channel 4 in our household—so the experiments were not long in progress! The "ball-park" figure of 0.05 µH of inductance for the resistor is reasonably close. The cal-

culated value of L for a typical resistor was $0.03~\mu\text{H}$. They are "spiral-cut" and the pitch varies slightly in production. Probably this explains the slight reactive quality of the dummy load resistors.

It might be possible, with a little experimenting and a different physical layout, to come up with a cancellation of most of these effects, and possibly bring the SWR down to 1.1 to 1 throughout the HF amateur

bands. We stopped short of this goal, since the load as it presently stands does an excellent job on all the ham bands 80 thru 15 meters. It should be possible to feed more power into the "dummy" if you place it outdoors on a cold winter's night. As it stands, you can feed the rf output from a 250 or 300 watt rig, key-down half the time, without additional cooling.

Tired of Dead Batteries?

Don't get caught with your battery down. Install an extra battery with little trouble.

Shortly after I first started mobile operation I experienced a pitfall that happens sooner or later being stranded with a dead battery (and sometimes in awkward locations).

I started to carry an extra battery but it was a nuisance using jumber cables and I was never sure how much charge was left in the extra battery. So I decided to hook it up in parallel with the main car battery.

I read some of the articles in the ham publications and most of them used complicated hookups with lots of relays to install the extra battery. One author even went so far as to use a relay to disconnect the extra battery when starting the car motor. To me this all seemed ridiculous.

Figure one shows the simple hookup I used. All the radio equipment (and some extra lights that I use a lot for camping and extended periods of mobile relay operation at night) are connected to the extra battery side of the relay.

With the relay coil being connected to the ignition switch several bonus features are to be had, namely:

- 1. Operation with the motor off drains only the extra battery, leaving the mean battery to start the motor.
- 2. Both batteries supply current to start the motor, a big bonus on those cold winter mornings.
- 3. Both batteries are charged automatical-

*Ignition switches vary . . . use your ingenuity to get the results desired. In the later cars it might be best to connect to the wire going to the spark coil.

- ly. No special adjustments to the voltage regulator, etc., are needed.
- 4. Any thing left turned on overnight will drain only one battery.
- 5. When a battery "goes west" of old age (which seems to happen anytime or anywhere) the other battery will start the car and get you home.

I find it best to keep the best battery in the front (factory installed position). This system has worked out perfect for me in three cars and I am now installing it in my fourth car.

It is a great comfort to know I won't be stranded during extended mobile especially in Civil Air Patrol operation where it is common to operate continuously in one spot for several days. In this type of operation I operate usually two frequencies at the same time and also monitor other services as the situation might require.

For the price of a battery and a relay (much cheaper then a alternator system and in many ways even better) you can have a lot of freedom from worry about the "power source" in your car.

W3WUA's simple solution to the problem of dead batteries.

The Easy Way to Decibels

One of the most often used yet little understood terms in amateur radio is the decibel, commonly known as the dB. Articles and introductions to this not-too-complex topic are generally presented with the formula:

$$dB = 10 \log \frac{V_s}{V_1}$$
 for power and

$$dB = 20 \log \frac{P_a}{P_i}$$
 for voltage

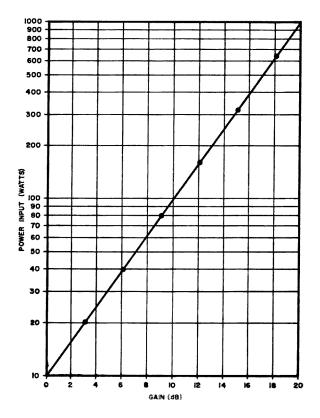

Each has its use in amateur radio. However, the amateur not versed in mathematics and logarithms, when confronted with these formulas, usually backs off. Most hams, therefore, are content with the knowledge that an increase in the number of decibels is desirable and that a loss in the number of decibels is not.

This knowledge suffices for all practical purposes. However, considering the many times decibels are used in the operation of a station, it behooves the amateur to become more familiar with this elusive term. The amateur may consider increasing the power of his station or changing antennas. How many decibels will this change represent? Will it pay to increase transmitter power or install a more efficient antenna system? This article will help to answer these questions without the use of complex mathematics.

Decibels as such are not an absolute quantity. They refer to a change. This change expresses ratio whether it be current, voltage, or power. The ratio means nothing until some reference level is established. Once the reference is set this reference is considered zero (0) dB. For example, some communications engineers may use 6 milliwatts (.006 watt) as reference

while others will use 1 milliwatt (.001 watt). The reference level or zero dB, when used in amateur radio, is whatever the amateur starts with.

For the purpose of illustration lets assume Joe Ham has a 10 watt rig which is operating under ideal conditions (no losses). It must be realized that there are always losses. However, for the purpose of facilitating the understanding of decibels all conditions will be considered ideal. The power input to the final (the 10 watts) is the reference level or zero db. Any station changes to increase power will be referred to this starting power. If the station was running a 100 or 1000 watt transmitter, this would be the 0 dB or refer-

SUB-MINIATURE SOLID STATE TV CAMERA

FOR CLOSED CIRCUIT OR AMATEUR TV

THE VANGUARD 501 Is a completely automatic closed circuit television camera capable of transmitting sharp, clear, live pictures to one or more TV sets of your choice via a low-cost antenna cable (RG-59U) up to a distance of 1000 ft without the need for accessories or modifications on the TV sets. The range can be extended indefinitely by using line amplifiers at repeated intervals or by using radio transmitters where regulations permit.

There are hundreds of practical uses In business, home, school, etc. for any purpose that requires you or anyone chosen to observe anything taking place anywhere the camera is placed. Designed for continuous unattended operation, the all-transistor circuitry of the 501 consumes only 7 watts of power.

SPECIFICATIONS:

- Measures 23/4" x 4" x 7" (excluding lens and connectors).
- Weighs 31/2 lbs.
- Operates on 100-130 volts 50 or 60 cycles, 7 watts.
- Tested at 10° to 125° F.
- Advanced circuitry utilizing 35 semi-conductors most of which are silicon.
- Field effect Input circuit for minimum video noise.
- Resolution guaranteed to exceed standards set by 525 line TV receivers.
- RF output 30,000 microvolts adjustable for channels 2 to 6.
- Video output 1.5V p-p composite with standard negative sync (random Interlace).
- Viewable pictures obtainable with Illumination as low as 1 ft. candle.
- Vidicon controlled light compensation; 150/1.
- Adjustable iris en lens enables use in bright sunlight.
- New long life, sub-miniature vidicon with spectral response similar to Type 7735A.
- Electronically regulated power supply and thermally compensated circuits eliminate change in picture quality when line voltage and temperature fluctuate.
- All parts guaranteed for 1 year (except for open filament on vidicon or breakage).
- Fast, low-cost service always available from our factory in Hollis, N.Y.

Pre-set adjustable controls include the following: Video gain, video compensation, pedestal level, target voltage, beam voltage, beam alignment, electrical focus, horizontal frequency, horizontal size, vertical frequency, vertical size, vertical linearity, modulation and RF frequency output.

ence level.

Any contemplated change in the transmitter power will result in a change in decibels or a change in the power ratio. Joe ham decides to increase his power from 10 watts to 20 watts. What will the result be in decibels? Referring to Fig. 1 will disclose that the increase will be 3 dB. Observe that to obtain an additional 3 dB gain the 20 watts must be increased to 40 watts. Therefore, an important point to remember is: each time the power is doubled the gain is increased by 3 dB. Conversely a 3 dB loss reduces the power by ½. Knowing these facts any multiple of 3 dB can be calculated. Accordingly, let's see how this works out for an arbitrary value of 15 dB.

dB gain watts	0 10	$\frac{3}{20}$	6 40	9 80	$\begin{array}{c} 12 \\ 160 \end{array}$	15 3 2 0
dB loss	0	3	6	9	12	15
	10	5	2.5	1.25	0.625	0.3125

In order to extend our ability to calculate dB's it will be advantageous to review some basic arthmatic. When a number is multiplied by 10 you affix a zero to the number. Multiplying by 100 you affix two zeros, etc. This is known as shifting the decimal. Dividing by any multiple of 10 moves the decimal in the opposite direction. The ability to shift the decimal is all that is required to be able to calculate decibels in multiples of 10.

Calculating decibels in multiples of 10 is simple if you consider the reference as 0 dB, if it is desired to determine the increase in power for 10 dBs we've changed the reference 0 to 10 by putting the digit 1 before the zero. Essentially this digit (1) tells you to add 1 zero to the reference. Therefore, the 10 watts with a 10 dB increase becomes 100 watts. For 20 dB the digit before the 0 is 2. This digit (2) tells you to add 2 zeros. The 10 watts with a 20 dB gain will become 1000 watts. In order to clarify this let's utilize this information to make a chart.

dB gain 0 10 20 30 40 50 watts 10 100 1000 10000 100000 100000

To consider losses. It is best to consider that the digits before the zero indicates the number of places the decimal must be moved to the right. Observe the chart below.

dB loss 0 10 20 30 40 50 watts 10. 1.0 0.1 0.01 0.001 0.0001

Places deci-

mal moves 0 1 2 3 4 5

Thus far we are able to calculate decibels in multiples of 3 dB and 10 dB. Combining these two facts with addition and subtraction we are now able to determine the gain or loss for any number of decibels. To ascertain that we do, we'll find the value for any number of decibels between 10 and 20 still using the original 10 watts as zero reference. Starting with 10 dB gain adds a zero to our reference, increasing the 10 watts to 100 watts. Each additional 3 dB gain doubles the power.

Decibels 0 10 13 16 19 watts 10 100 200 400 800

Now starting at 20 dB the 10 watts with two zeros becomes 1000 watts. Each 3 dB reduces the power ½.

Decibels 0 20 17 14 11 watts 10 1000 500 250 125

The only values we have not determined are values of decibels for 12, 15, and 18. These values are multiples of 3 and can be calculated by utilizing the method de-

scribed previously.

The practical application of decibels in terms of power, can now dictate the advantages or disadvantages of station changes. Increasing transmitter power is a one way street. The old adage; you can't work what you can't hear is applicable. Therefore, when looking for db gains; travel the two way street via the antennas. Improving antenna capabilities increases the number of decibels in both the transmitted power and the received signal.

When antenna gain is specified by the manufacturer, the gain is based on what the beam will do in comparison to a dipole under the same conditions. If a beam rated at 8 dB gain is replaced by one having 15 dB the gain is 7 dB. Stacking antennas increases the gain 3 dB. Raising the antenna an additional 30 feet will result in a 10 dB gain. These facts are presented so that you can start using this method of calculating decibels in terms of power the easy way.

NEW! IMPROVED! SOLID STATE FREQUENCY CONVERTERS

Priced from only \$14.95 to \$39.95

OVER 5000 FREQUENCY COMBINATIONS FROM .45 MC TO 475 MC AVAILABLE FROM STOCK.

MANY NEW MODELS TO CHOOSE FROM OFFERING A TOTAL OF THE FOLLOWING: Crystal control, variable tuning, UHF epitaxial transistors, FET transistors, noise figures as low as 2.0 db, full wave varactor diode transistor protection, sensitivity better than 2/10 microvolt, fully shielded oscillators and band-pass filters to eliminate spurious frequencies, zener diode voltage regulation, 6 to 12 volts positive or negative ground, slug tuned coils, double tuned R.F. stages, tuned mixer stages, wide band I.F. amplifiers. All this plus the highest quality components carefully assembled, tested, and quaranteed.

We have exactly what you want at a lower price and better quality than you can obtain elsewhere. See our new multiple oscillator converters for monitoring two or more frequencies simultaneously!

24-hour special delivery service available on many models.

Send for your free 1967 converter catalog.

The Highflyer

An All-Band SSB-CW Receiver

This article is about a home-brew ham band receiver covering the 80-40 20-15 and 10 meter bands in 200 kHz tuning steps. Before discussing the receiver a few reflective thoughts are presented on the idea of home-brew construction in general.

Most amateurs should be able to build a receiver if they have the time, a few instruments and tools. Picking circuits to use out of the handbooks may not always work for a specific application, and it may be necessary to try several circuits before finding one that works right.

Home constructed gear probably has some faults but if you really take a close look at most manufactured gear there will be oscillator harmonics across spots in the dial, images and signals feeding through from other bands. A ham can do a comparable job and have a lot of fun building which should be part of our hobby.

Some people spend all of their time building intricate model ships, airplanes or play cards. I spend my time building impossible ham gear. Perhaps the urge to build is the desire to do something creative instead of just yakking on the microphone for a change. The fallacy that you have to be experienced to work out ham gear is wrong. Anyone can gain enough experience if they just

72 73 MAGAZINE

work at building for a while, but they must build and try various circuits. Sometimes it helps to keep notes on the circuits tried, but I am always too busy to keep notes and find myself making the same mistakes over again. Fortunately I am clever at filling up chassis holes. After months of building and the unit is finished I may never turn it on again, but after completing this receiver I can't wait to get home and turn it on to marvel how well it works and that I was able to build it. It is a fine feeling that is not present turning on a manufactured receiver. Visitors stop in to listen, and this way hams from all over the world at one time or another come by the shack.

Besides personal contact one way amateurs can exchange circuits and transmit or expand his knowledge from generation to generation is through magazine articles. If amateurs don't take advantage of this and continue their mad pace to buy all manufactured equipment, our old concept of ham radio will have changed. Fortunately we have 73 Magazine as a medium to pass on information that is not staff written. One can read and does not always have to build the item in the article to gain some new idea. With this thought, the following receiver article is presented, and I hope someone has the

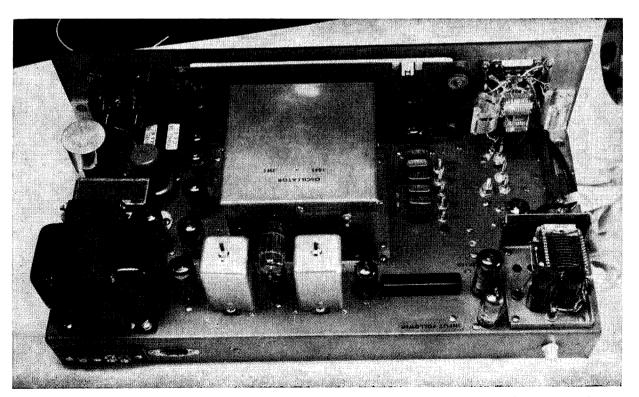

time and a few bucks to buy the parts and give it a try.

Theory

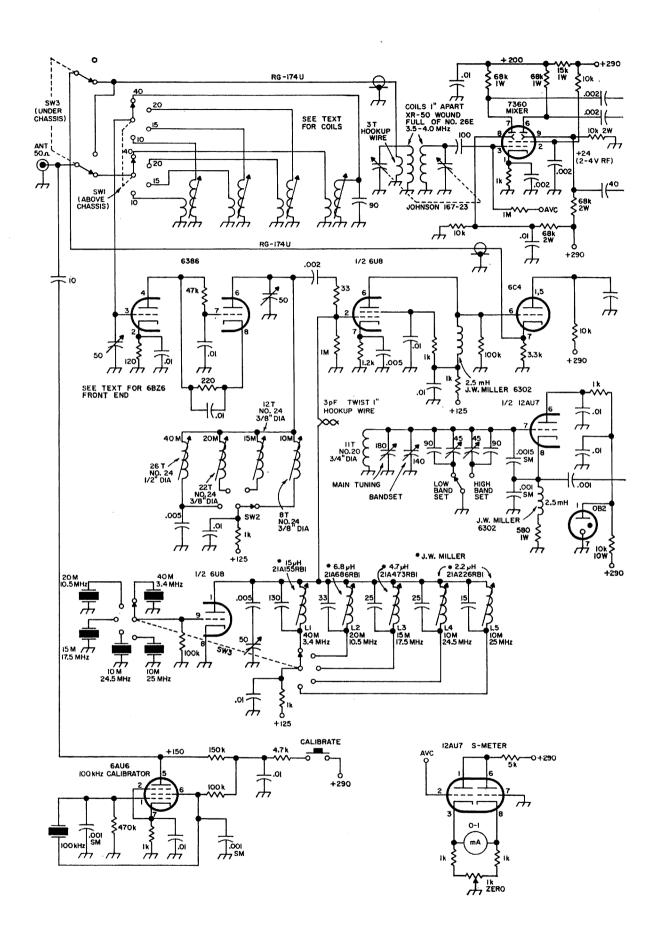

Basically this receiver is a simple 80 meter receiver into which converters are fed for the HF bands. On 80 meters the panel switch feeds the 52-ohm coax antenna input directly into the 7360 mixer input tube through two tuned circuits which are loosely coupled. This is necessary along with the shielding of these coils to prevent signals 455 kHz away, such as fishing boat frequencies, from coming in on the 80 meter ham band. A VFO signal of 3045-3345 kHz and 3345-3545 Khz is injected into the 7360 mixer tube. The mixed output of this tube is 455 kHz and is coupled directly into the Collins mechanical band pass filter. The signal is then amplified by two stages of if amplification controlled by AVC; then the amplified signal is detected in a product detector and audio amplified.

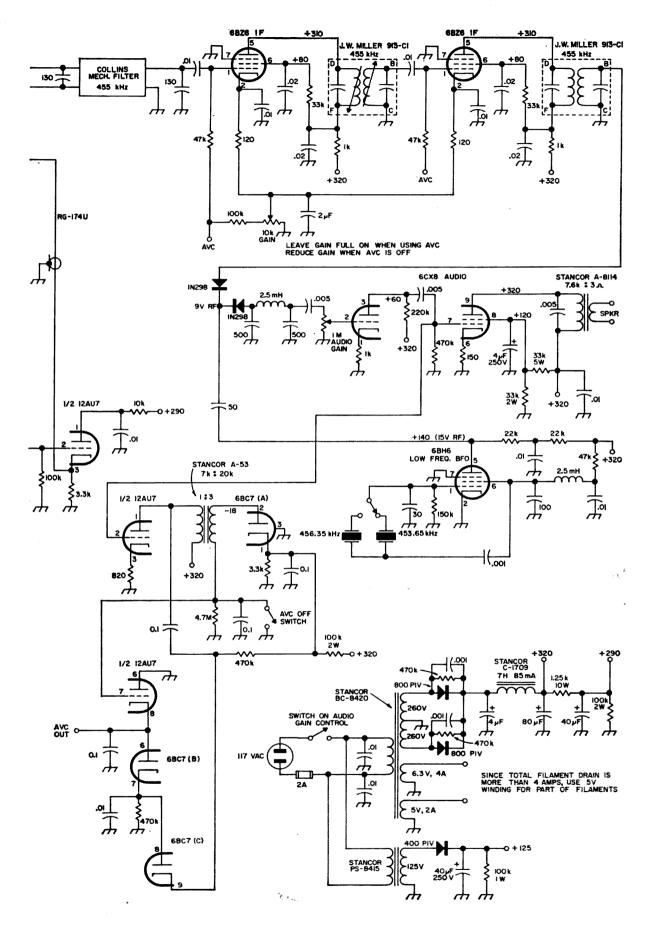

Construction

On the 40 20 15 and 10 meter bands a crystal-controlled converter preceded by a cascode rf stage feds into the 80 meter receiver via a cathode follower which matches to the high impedance output of the 6U8

Back view of the receiver showing input on the right side, mechanical filter, if strip, and power transformer on the left. The VFO is enclosed in the large box in the center of the receiver.

converter plate circuit. The forty meter band tuning starts at 3600 kHz, this idea was used to keep from having to use a 3500 kHz crystal which would be annoying if it was operating on its harmonic of 7000 kHz during tuning.

The AVC uses the Luick system of audio amplified fast attack AVC, one of the best circuits for receiver design.

The most expensive parts are the Collins Mechanical filter, number F455-21-6626, a 2.1 kHz bandwidth filter costing \$26 obtained directly from Mr. B. Cornes, Component Sales, Collins Radio Co., 19700 Jamboree Rd. P.O. Box C, Newport Beach, Calif. and the Eddystone dial #898 ordered direct from Mr. F. N. D. Harris, British Radio Electronics Ltd. 1742 Wisconsin Ave. NW, Washington, D.C. These two pieces are the heart of the receiver; after making the decision to purchase them the next thing is to buy a 8 x 17 x 2 inches California Chassis type A-109 and a PA-14, 8% x 19 inch panel. I cut my panel down to 6½ inches high by 17 inches long for a more pleasing appearance. A few shields are necessary and 16 gauge aluminum can be bent in a vise with two blocks of wood or maybe you know someone with a hobby brake or can get a metal shop to do it for you. LMB boxes can also be sawed up to get shields. Once the major portion of the holes have been punched a professional appearance can be given the chassis by dipping it in chemical dye obtained from a chemical supply house under the trade name Oakite metal dve. The chassis is first cleaned with lacquer thinner and dipped in lye water which is warm. This cleans the metal. This is washed off and dipped in Oakite bright dip and washed again. The chassis is then put in the Oakite gold metal dye for 15 minutes and washed off. Plastic containers for dipping can be bought in the Super-Markets.

Metal working requires a few tools. A % inch, a % inch, and a 1% inch Greenlee punch are almost necessities. A clear drill for 4-40 and 6-32 screws and a % inch, % inch and % inch bit for metal are also needed.

Probably the first electrical circuit to build is the power supply so that voltages will be available to check out the circuits as they are built. The VFO should be built on the chassis next so that you will know how much available space is left to lay out the parts. Next after the VFO, wire the audio stage and check it out, then the if system. The grid return to the if's can be grounded to test it out since the AVC has not yet been built. Along with the audio and if put in the diode detector and wire up the low frequency crystal oscillator for the BFO. When this is finished a 455 kHz signal can be fed into the if front end and detected and if's peaked up. If the mechanical filter has not arrived that spot can be jumped out with a .005 µF capacitor between the 7360 mixer and the if tube for testing. After the 7360 has been wired in the AVC can be built, leaving the VHF converters until the receiver is operating correctly on 80 meters.

Power supply

The load on the 6.3 V, 4 amp filament winding is heavy and some of the tubes such as the crystal oscillators and others can be run off the 5 V winding without any bad effect. The extreme drain on this transformer might warrant using a larger one but as an assist to the HF isolation the drain was eased by using a 125 volt 15 mA instrument transformer for the converter and rf stage. Stancor type PS-8415 was used here.

Two 400 piv diodes were put in series for rectifiers in each arm of the transformer. They are cheaper than diodes with higher piv's. To keep transients from puncturing the diode rectifier a .001 µF disc ceramic capacitor is placed across each diode rectifier along with a 470 k ½ watt resistor. For complete elimination of hum a 4 μF condenser was used as an input filter before the filter choke. It was necessary with a large loud speaker with good low frequency response to keep it free from hum. Power for the VFO is obtained from a 105 volt OB2 gas regulator. The series resistor should be adjusted so that at least 10 to 15 mA does it.

Audio system

The audio system uses one tube which gives plenty of audio gain. If the audio is weak is is not the fault of this stage which is a 6CX8 triode and a pentode in one bottle. The screen voltage should be held constant at not over 150 volts by a voltage divider. Our voltage was 120 volts. A .005 μ F capacitor is placed across the

primary of the audio transformer to prevent self oscillation from building up and damaging the audio transformer winding insulation or to prevent arcing from occuring across the tube socket pins.

By now you will need some knobs to adjust controls. The fancy knobs used on this set were Davies type 1913 black knobs with white indicator lines. They will have to be ordered from Littrell Western Sales, Inc., P.O. Box 23645, 3121 East Twelfth St, Los Angeles, Calif. 90023, attn. Mr. M. Morita. Radio parts stores do not seem to stock anything out of the ordinary and it's worth the effort to get these and make the receiver look better.

The triode portion of the tube normally uses a 150-ohm resistor but in this instance there was so much gain the current was reduced by inserting a 1000 ohm resistor.

Shielded wire such as RG-174U was used to wire the gain control on the panel. Just ahead of the triode tube is a filter made up of two 500 pF capacitors and a 2.5 mH rfc. This filter prevents any 455 kHz signal from feeding into the audio system. A 68 k resistor could be used in place of the choke but the cut-off characteristics of the filter will be changed slightly.

Product detector

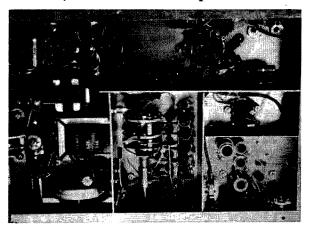

Of all the various product detector circuits tried this two diode circuit performs as well as any, however, germanium diodes must be used. Just any diode won't work. The diode used has to have a lot of leakage to prevent charging up and blocking. The 1N295 or 1N67A are common ones used in this circuit. For loud signals proper mixing is secured in these diodes with 5 to 12 volts of rf from the crystal oscillator. Anything under 5 volts will sound distorted if a strong signal is being received but will sound okay on weak signals. Injection was measured by using a signal generator and varying the diode injection voltage and listening to its performance at the various voltages for weak and strong signals. This rf voltage was measured with an rf probe in conjunction with a Heathkit VTVM.

The if strip

The first thing to do when building the if strip is to open up the if can and squeeze the coils to within ½ inch of each other. This operation is not recommended by the J. W. Miller Co. because the coil now be-

comes overcoupled and might be a reflection on their product if it gets into wrong hands. I reasoned that I needed the extra gain to make up for the loss in the mechanical filter, and I did not want to add another if tube. Since the selectivity was obtained in the filter it was felt that the ultimate in selectivity was not needed from the if cans. Squeezing the coils together is difficult to accomplish without damaging them. Bill Courtney at the J. W. Miller Co. would rather wind the coils for you than have you damage them. If you already have coils, take a razor blade and scrape the glyptol from each side of them on the top coil only where it is glued to the fibre form. Now with a camel hair brush paint dope thinner around the base of the coil to soften up the cement under the wire. Next place a piece of % inch thick wood between the coil by first drilling out a %" hole and sawing the block in two parts so that it fits snuggly around the fibre tube. Take another piece of wood with a 1/4 inch hole and slip it over the fibre tube after the slug has been removed. With a quick snap the coil should slide up against the wood between them leaving the coils 1/2 inch apart. Do not try this process without using the spacer because the wire will come out from inside of the coil.

Many hams have trouble trying to build an *if* amplifier without oscillation or regeneration taking place. First all parts should be returned to one ground lug on each *if* tube, although it never seems to help the problem. In most cases a 22 k or 47 k resistor can be put across the winding of the *if* transformer to stop oscillation or

Bottom view of the receiver showing the converter output coils in the lower right hand corner. The box in the middle contains the crystal switch and coils. To the left is the converter power supply.

by tapping down on the secondary winding for the grid. Most military receivers do this and the Miller has tapped coils for this purpose. Many commercial builders increase the 6BZ6 cathode resistor to 120 ohms to cut down on the gain. I found building this receiver the stage is absolutely cool by reducing the series resistor to the AVC line to 47k in conjunction with squeezing the coils together which lowers the "Q" grid is looking into. No resistors were needed across the coils and we were quite happy to find no regeneration when peaking the if cans in this receiver. Good decoupling with 1 k resistors and .01 µF capacitors in the supply leads also help to isolate feedback.

7360 mixer stage

This tube was chosen because it eliminates the need for an rf stage and takes large input signals. It is linear and performs mixing by switching between two output plates operating in push pull and is inherently balanced against the input signal frequencies. The oscillator injection voltage can be anything from 1 to 10 volts. The tube does have some critical aspects in transmitters where the accellerator voltage changing can unbalance the carrier. In receivers, this is not critical except that proper voltages should be used. There must be 175 volts on the screen or accellerator and 20 to 25 volts on the deflection plates. The main supply to the tube should be set at 200 volts to give 150 volts on the plates. The voltage actually came out a little higher in this receiver. The tube couples easily into the mechanical filter via the .002 µF capacitors.

Reference data on the cross-modulation and overload characterics can be found in QST.¹

VFO injection to the mixer is not critical. One to five volts is satisfactory. Since there is no rf tube ahead of the 7360 adjacent signals 455 kHz away in the marine band might feed in if they are not attenuated by a good shielded front end coil. 80 meters is the only band we have to worry about this because the image is 3.5 MHz away using the converters on the other bands.

To gain this good selectivity on 80 meters a large coil could be used, but that takes up a lot of room. It was found two XR-50 National slug forms wound full with number 26 wire and tuned with a split stator capacitor make a good filter. The coils were placed adjacent to each other and peaked up to the capacitor and moved away from each other to about one inch where the double hump effect went away and left a nice sharp tuned circuit. The image should be down 60 dB. The coils were placed in a box to prevent any pick up of signals by themselves. Any split-stator capacitor could be used but the E. F. Johnson butterfly type dual #167-23, 50 pF each section took up little space. It was necessary to shunt another 40 pF across each section so that it would tune the 80 meter band, which can be set in the middle of the condenser range by adjusting the slugs to maximum signal strength.

AVC was used on the 7360 to good advantage since it limits the signal going into the mechanical filter, which would over load and ring if the signal peaks were too high.

AVC system

The receiver should be tried out before hooking on the AVC system by grounding all of the if and 7360 grid resistors. Once the AVC system is hooked on there should be a negative AVC voltage of 0-20 volts. The Luick AVC system was chosen for this receiver after having used several systems in other receivers. It works the best for fast attack and slow decay. The hold-up time is set by the 0.1 μ F capacitor and 4.7 M Ω resistor. If this resistor is made smaller VOX operated SSB stations will make the receiver pump and sound funny. This value can be lowered for CW but so far there has been no need for it.

The AVC voltage is taken off the product detector and is amplified by a triode tube, then rectified and passed on through another diode to charge up the storage capacitor, a 0.1 µF capacitor, which stays charged until discharged to ground by the other triode tube. A strong audio signal provides a negative voltage of 0-20 to control the if's and 7360 tubes. When there is no audio signal coming, the grid of the triode goes positive and allows the charge on the capacitor to leak off to ground. This grid control is also effected by the

⁷³⁶⁰ Mixers in the 75A-4 p. 18 July 1964 QST.

0.1 μ F and the 4.7 M Ω resistor. For faster or slower leak off the value of this resistor can be increased or decreased, changing the time the voltage will be stored and the 0.1 μ F holds the triode off. A discussion of this circuit is in the ARRL Handbook, if you have trouble.

"S" Meter

The "S" meter can be taken off from the AVC line and it will be a measure of the AVC voltage. Zero level can be set with no signal and by adjusting the balance potentiometer. The scale reading was adjusted for a strong signal at R-9 by changing the value of the cathode resistors. Maximum reading can be set by either adjusting these cathode resistors or by changing to higher gain tubes such as the 12AT7, or 12AX7 if the 12AU7 has to low a gain and you don't want to fuss with the resistors. It is important to use no grid return resistor on the tube where the meter is attached to the AVC line or it will upset the time constant of the AVC action. Thus vou will note no grid resistor is used in this circuit.

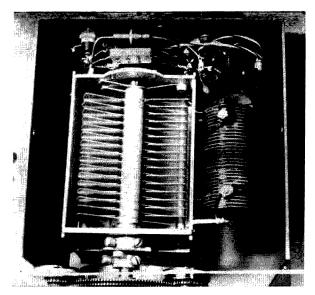

Tuning of a signal produces a negative voltage on the AVC line which causes currents in the cathodes of the "S" meter amplifier to unbalance the circuit. The meter will read the unbalanced or difference voltage. The resistor in series with the tube plates can also be adjusted larger or smaller depending on the meter readings.

The "S" meter is a Lafayette Model 99-2514, 0-1 mA with illumination. Instructions for lamp connection is inside the box.

VFO

The VFO oscillator tunes both 3045 to 3265 kHz and 3315 to 3545 kHz, using the surplus ARC-5, 180 pF capacitor. Tuning barely covers the band. The ham bands are covered in two steps of about 250 kHz each. The oscillator was switched with a three position switch. The third section uses no padders and covers 4000 to 4200 kHz. The trimmer on band two was set so that the dial matched 3720 on zero and 3500 on band one.

A cathode follower was used after the VFO to separate any loading effect on the oscillator. All signals are carried via RG-174U coax. The coil was bolted to the capacitor so that there would be no mechanical motion. The tube is mounted in a horizontal

The inside of the VFO box assembly.

position on the back of the box. Calibration should be done with the cover bolted in place. With an LM frequency meter the calibration is easy. Otherwise someone on the air with a Collins transmitter could give calibration marks or surplus crystals could be used for check points. The rf output to the mixer can be varied by changing the 40 pF capacitor in series with the cathode follower output. Anything between 2-4 or six volts will be satisfactory for injection. When the VFO was finished the coil was doped with Q dope, although, the wire was wound in grooves. Air-Dux bulk coil could be used if no fibre forms are available.

This circuit is so swamped with high capacitance that the stability of the circuit is very good, and there does not seem to be any drift problem noticed. Use silver mica capacitors in the tuned circuits in conjunction with the air capacitors.

Low frequency oscillator

Many low frequency crystal oscillator circuits were tried using surplus crystals ground to 453.650 and 456.350 kHz. The only circuit which worked satisfactorily is the one shown in the schematic. Perhaps the wave form on the oscillator plate with no tuned circuit leaves much to be desired for a perfect sine wave, however, the frequency is correct, and it is satisfactory for the product detector injection.

Sluggish low frequency crystals need a large rf choke in the screen lead, and most circuits use a 60 mH choke. This circuit worked with a 2.5 mH choke taking up less

space. Sometimes the 30 pF capacitor from grid to ground may have to be varied to obtain oscillator but not the 100 pF from

the screen to ground.

New crystals can be bought from Mr. P. M. Freeman at International Crystal, 18 North Lee St., Oklahoma City, Okla., ground to 453.650 and 456.350 exactly but they cost \$8.00 each. It is important to have these crystals as close to these values as possible so that the band-width of the receiver is 2.7 kHz wide at the 20 dB down points. Otherwise the voice signals will sound distorted.

The other solution for the proper crystal is to buy surplus crystals and edge-sand them down to frequency. JAN*, which advertises in 73 Magazine, sells these crystals for 50 cents each. A channel 45 and a channel 329 will work but sound a little funny. If you're brave, buy a handful and sand them down, tuning the receiver until they sound good. The best way would be to check the frequency with a counter.

Changing the frequency can be done as follows:

Put a piece of fine emery paper on a flat surface and tape it down. Place the crystal in the left hand holding the prongs with the fingers of the left hand, and holding the crystal itself with tweezers in the right hand. Draw the crystal edge toward you moving both hands together making a scratch about five inches long. Drag the crystal across the paper about ten times and it will move it about 600 Hz higher in frequency. This process is very touchy and if the tweezer slips, the crystal will twist and break the fine wire, it might pay to take the time and make a wooden holder from a clothes pin or two pieces of wood, but it can be done.

The following are surplus crystal channels:

Channel 326 - 452.777 Channel 45 - 453.707 Channel 327 - 453.166 Channel 46 - 455.555 Channel 329 - 456.944 Channel 47 - 457.407

I suppose other methods could be used to vary the crystal frequency. Shunting capacitors across the crystal never worked very good and did not change the frequency enough. With patience you can get the Channel 327 and Channel 46 on the spot.

You can get an idea what a crystal off frequency sounds like by plugging in some of the above mentioned crystals.

The HF Crystal Oscillator

It is recommended that the International crystals of .01% tolerence be used in this oscillator so that the dial calibration will be on the mark. International FA-9 crystal fits into a FT-243 crystal socket. All of the crystals will oscillate in a standard triode oscillator with a tuned plate tank, although the output may fall off slightly at the higher frequencies. It is difficult to specify the exact value of the slug coil and tuning capacitor to use with each coil because the lead length will be different used by each constructor. Tuning is critical. These coils can be grid-dipped with the meter when they are all in place and then adjusted for capacity after applying power and noting where the slug comes to rest. The slug should be set just back of maximum output because the oscillation will drop out if too near maximum tuning. An rf probe can be used to peak up these coils or a full scale meter section of the grid-dipper. Using the probe a test point can be put in the chassis and coupled to the coils with a 10 pF capacitor to make it easy.

VHF Converter

You can wind your own coils using #26 wire if desired. XR-50 forms are nice if you have room.

This section which looked to be the most simple turned out to be the most difficult part to make work properly. The first try used a 7360 but it was necessary without the rf stage and output coils to use a high Q coil circuit. The coil being so large picked up 80 meter signals like an antenna and fed in the 80 meter signals on all bands. To prevent this an rf stage was added and the 7360 replaced with a 6U8 mixer. Reducing the size of the coils and shielding them stopped the pick-up and prevented oscillation from occuring. To further prevent coupling a separate power supply was used for this section and it was needed any-

way because of the overloaded power transformer on the rest of the receiver.

On the upper deck of the receiver was installed a switch to change the input coils to the rf stage. Oscillations could not be stopped when all of the switches were ganged together. The coil dimensions are as follows:

40 Meters-34 inch dia., 15 turns, Link, 6 turns. Air-Dux Bulk Coil #632

20 Meters-34 inch dia., 11 turns, Link, 4 turns. Air-Dux Bulk Coil #616

15 Meters—% inch dia., 8 turns. Link, 3 turns. Air Dux Bulk Coil #516

10 Meters—5% inch dia., 6 turns. Air Dux Bulk Coil #516 6 turns. Link, 2

These coils were mounted on five lug terminals, with the ten meter coil just soldered across the Centralab ceramic wafer switch, a double pole six position switch, Type PA3.

The output coils of the cascode converter are the grid input to the converter, and are separated from the converter grid by a shield. The 33 ohm resistor in series with the grid helps prevent overloading.

The output coils are as follows:

40 meters: 26 turns en. #24 wire wound on a

½ inch slug coil form.
20 meters: 22 turns en. #24 wire wound on a % inch slug coil form.

15 meters: 12 turns en. #24 wire wound on a

% inch slug coil form.

10 nieters: 8 turns en. #24 wire wound on a % inch siug coil form.

Coils are all grid dipped and adjusted in the circuit

The XR-50 coil forms can be used if desired but the smaller coil forms fit better taking up less space. The 50 pF variable capacitor completes it circuit through a .005 μF capacitor between the bottom of the coils and ground lug. The switch for these coils is located underneath the chassis. This switch is used by itself, the other half is not used. The switch for shifting the converter output to the cathode follower is under the chassis and is part of the crystal switching switch.

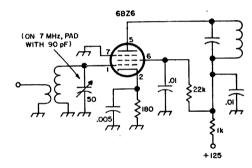

RF Stage

The rf stage is one of the most difficult things to build in a receiver. Any type of coupling between the grid and plate brings on oscillation. The rf stage should not oscillate when the antenna is disconnected from the set, and the input and output tuning capacitors are tuned. For complete separation the antenna input coils should be mounted on top of the chassis in a box if possible while the output coils are mounted underneath. The grid should have a piece of tin cut from a coffee can around the

grid pin, which can be soldered to the center shield of the socket. Put the feedthrough insulator right at the grid pin. Shield the output coils from the grid if possible.

Generally 40 meters will oscillate while the other bands are clean. This is due to insufficient capacitance tuning on that coil. A 90 pF capacitor was soldered across the coil and turns peeled off so that the variable would peak it to 40 meters. This is done with the antenna on because it will add some capacitance to the tuned circuit and which will be different than when it is taken

The 6386 cascode tube is expensive and may not be desired by some constructors. An alternate circuit using the 6BZ6 is shown. The coils are the same. Actually on the lower bands no difference was really noted between the two circuits as far as sensitivity or noise was concerned. The 6BZ6 gives a little more gain which is needed on the ten meter band.

Alternate of amplifier that can be used in place of the 6386 tube. The same coil arrangement can be used. Put a shield around the grid.

Conclusion

The average amateur with a few tools and a VTVM and a grid-dip meter can have a lot of fun building this receiver. The receiver seems to work about as well as almost any on the market although it may take a few more switches to accomplish the band changing.

If you are in the area on your vacation and want to listen for yourself stop by. Just come in the back gate, and don't mind that madman running around in the backyard in shorts, barefoot, no shirt, hair uncombed, glasses down on the end of his nose, and waving a soldering iron. That's me, off on another construction project.

Geometric Circuit Design

A simple way to design electronic circuits is with geometry. This method avoids complicated math, yet is very versatile.

Over some years I have developed and have been using a new technique in circuit design. It is mainly graphic being based on geometry and avoids the abstractions found in complex algebra and many other forms of mathematics. The technique is deceptively simple and is based on only five basic con-

Henry, ex-W3AUE, is an electronic project engineer for Fairchild Hiller. He was licensed in the '20's.

cepts. Three of them are probably already known by circuit design people at every level. The other two are new and are needed to complete the design picture. These basic layouts are shown in Fig. 1.

At (a) two resistors are added in series. The same can be done with two or more inductive reactances on the XL axis or with two or more capacitive reactances on the Xc axis. At (b) we have the fimiliar parallelogram which shows the impedance formed by an inductive reactance X1 and a resitor R1 in series. Likewise the same can be done with

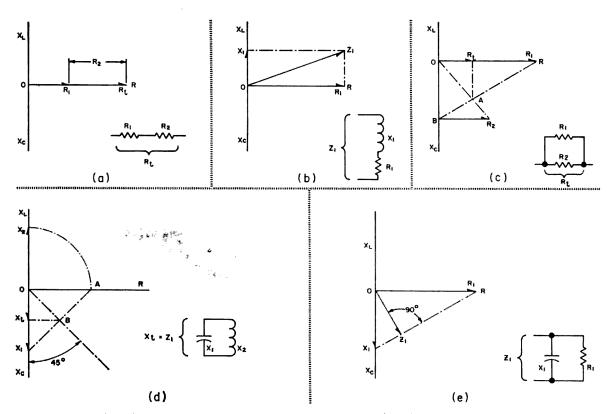

Fig. 1. Examples of geometric circuit design. Resistances are plotted on the horizontal axis marked R, capacitive reactances on the lower vertical axis, and inductive reactances on the upper vertical axis. (a) shows two resistors in series. (b) shows the impedance formed by a resistors and inductance is series. (c) shows the resistance of two parallel resistors. (d) illustrates a capacitor and coil in parallel. (e) shows a resistor and capacitor in parallel.

82 73 MAGAZINE

any Xc ar R or in fact any two impedances in series. The total value of any two resistors in parallel or any two like reactances can be found by the means shown in (c) of Fig. 1. While this one shows the R axis the same can be done with either other axis. Distance O-B is arbitrary and intercept A of the diagonal is projected up to find Rt. In Fig. 1 (d) a simple method of finding the parallel value of two opposite reactances. With the value of X2 as a radius, an arc is laid out to the R axis. At the intercept A a straight line is connected to XI. A 45 degree line is extended from the origin (O) as shown. At intercept B a line is projected horizontally to the X axis locating the resultant total reactance Xt. In any case the arc is constructed from the larger of the two reactances. Finally in Fig. 1 (e) there is shown the resulting impedance of R1 in parallel with X1. Here again this can be done similarly with any R and XL values.

It must be realized that any of these techniques can be worked in reverse that is if we have Rt and R2 in Fig. 1 (a) we can find R1. Likewise at (b) if we know Z1 and R1 we can easily find X1. In any case if we have any two we can find the third by these

simple geometric layouts.

Armed with these concepts we can now "jump off at the deep end of the pool" and emerge with meaningfull answers. Let's design a band pass "T" type filter to match 50 ohms to 200 ohms. Its schematic and layout is shown in Fig. 2. A scale of 50 ohms per centimeter* was used here and Rl is thus 1 cm long and R2 being 200 ohms is 4 cm long from the origin. We select X1 arbitrary and find Z1 immediately (see Fig. 1 (b). Z1 has equivalent shunt components Xh and Rh (See Fig. 1 (e). Since X2 depends on the value of X3 we cannot find it before we find X3 which we can find. Since Z1 and Z2 have the same equivalent shunt resistance Rh, a locus semicircle O to Rh has been drawn. This passes through both Z1 and Z2. Z2 is established simply by projecting vertically up from R2. See Fig. 1 (b). Now Z2 has equivalent components Xt and Rh which are in parallel. Again refer to Fig. 1 (e). Some reactance value X2 in shunt with Xt must form Xh. We find the value of X2 by projecting horizontally from Xh to the 45 degree line intercept B. We then project from Xt through B to A and draw an arc from A to

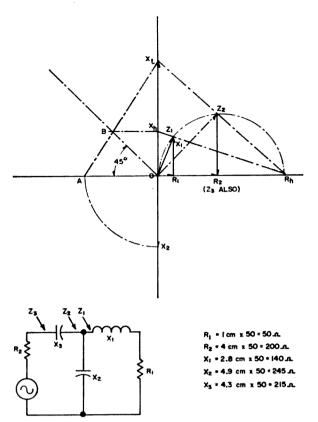

Fig. 2. Designing a band pass T filter to match 50 ohms to 200 ohms. The procedure is described in the text.

X2 about the origin. This establishes the value of X2. This geometry is performed on the left of the X axis to avoid confusion. This derives from Fig. 1 (d) working backwards. From the values Xt and Xh we have found X2

Continuing XI, X2, and X3 are measured in cm and multiplied by the scale factor (50 ohms pre cm). Values of each in ohms is shown in Fig. 2. If the design is for 27 MHz the component values are about 0.82µH for XI, 24 pF for X2 and 32 pF for X3. Components for any frequency desired can be found which will match these two resistances and deliver maximum power from one to the other.

Since we have a picture of all of the components and impedances in polar form it is possible to analyze or synthesize any complex circuit for phase shift, attenuation (voltage or current) and Q. With the value of Q we can determine the bandwidth.

The simplest way to match one transistor to another at a specified frequency is by means of an "L" filter. In Fig. 3 the schematic and layout are shown. Neglecting the distributed parameters we assume the in-

^{*}These drawings are reproduced ¼ size.

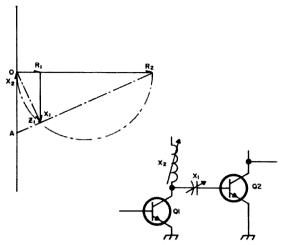

Fig. 3. Matching one transistor to another with an L filter.

put resistance of Q2 to be R1 and the output resistance of Q1 to be R2. These values must be found at the frequency desired. The locus circle with diameter O-R2 simplifies the construction of Z1 at right angles to the construction line R2-Z1, implementing the concept of Fig. 1 (e). In series with R1 we drop a perpendicular to the semicircle. This establishes Z1 that is the impedance looking from Q1 thru XI into the input of Q2. X2 extends upward from A to the origin. This is the reactance across R2 necessary to form Z1. Components can be evaluated as described above for 455 kHz or 50 MHz or any other frequency. Known distributed parameters are taken into account by adding them into the layout in the manner set forth in Fig. 1.

This technique can be extended to include the design or synthesis of delay lines transmission lines, "10" and "hi" pass filters, all coupling networks, and many mesh and bridge circuits.

Transceive with the GSB-201

The manual on the GSB-201 suggests another relay to operate it on transceive. Here is a way to do it with but adding a small transformer and rewiring a few parts. Thrown in is a cut-off bias supply for the amplifier in standby.

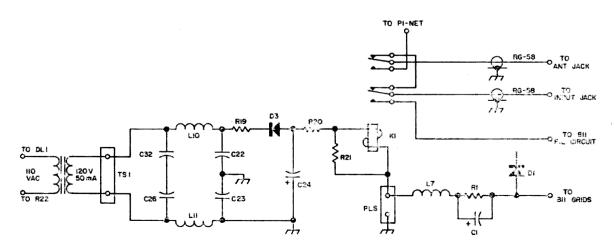

Modify the circuit as follows. Locate and reverse the D3 diode and C24 capacitor as shown. Remove the lead going to K1 from the junction of L11C23, C24. Ground the latter. Connect the lead going to K1 just removed to ungrounded side of PL5. Rewire K1 relay contacts as shown using R6G58 coax where needed. Add small transformer to circuit by connecting it to TS1 and primary to AC at DL1 and R22.

Be sure and put tape over TS1 on outside to prevent shock. Remove R21 only if you desire to speed up K1 operation. If this is done reduce value of C24.

Now we do all our switching by connecting relay contacts of transceiver to PL5. We find we have gained a built-in cut off bias supply. And by grounding this at PL5 we cause K1 to operate and cut amplifier into the cht. To disable amplifier and run transceiver only throw SI to off in amplifier.

Caution should be observed to keep leads short and well shielded. In my own amplifier I found no instability after this modification.

. Bruce Walther W9QAH

A Field Effect Transistor Converter for 10, 15 and 20 Meters

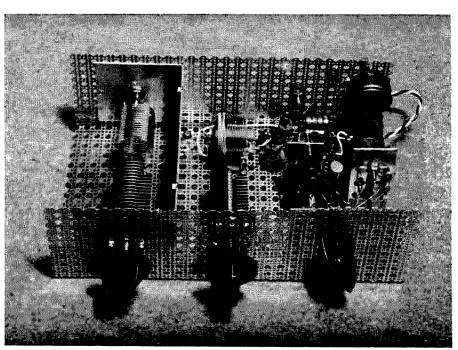

It is the author's goal to build a completely transistorized 10-160 Meter station. Lack of a low priced rf power transistor has postponed construction of the transmitter and, until recently, construction of the receiver was not attempted since it was felt that a vacuum tube front end was superior to any transistorized front end the author was capable of building. The availability of reasonably priced field effect transistors has changed the latter situation. With the high input impedance and almost perfect square-law transfer characteristic of the FET, the input circuit loading and susceptibility to cross modulation of a conventional transistor front end are easily avoided. Accordingly, the first step in building a receiver, designing and building a 10-20 meter crystal-controlled converter, was undertaken.

The converter schematic is shown in Fig.

1. Motorola 2N4224 FET's are used as the rf amplifier and mixer, while a bipolar 2N1180 is used as a transistor oscillator. A pair of Motorola MPF105's could probably be substituted for the 2N4224's, at a third of the cost, but this has not yet been tried.

The rf amplifier is designed to provide only enough gain to override any noise generated in the converter, so as to minimize susceptibility to cross modulation. This small amount of amplification, in conjunction with the sharp tuning characteristics of L₁-C₁ and L₂-C₂, yields a front end that is every bit the equal of its vacuum tube counterpart.

Mixer injection is accomplished by means of a "gimmick" capacitor connected to the mixer gate. Source injection was found to be satisfactory, but was not used because of the bandswitching problem it introduced: another switch section and a long lead to the mixer source were required. Source in-

Top view of the converter. Note that the input circuit is shielded. Photo by Chuck Marshall.

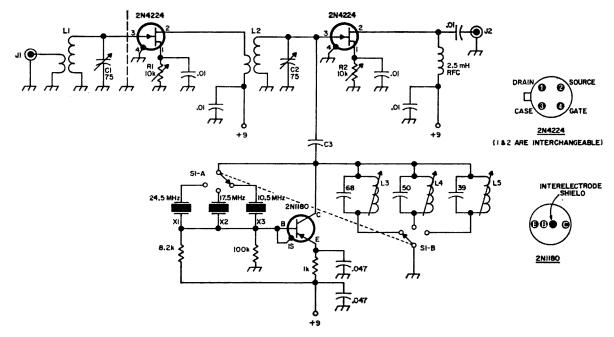

Fig. 1. Schematic diagram of the FET converter for 20, 15 and 10 meters.

jection would be preferable if local oscillator radiation proved to be a problem, since it places two FET's between the oscillator and antenna rather than one, as is the case when gate injection is used. (The reverse transfer capacitance of the 2N4224 is 2 pF compared to a grid-plate capacitance of 0.02 pF for the 6BZ6 pentode, a common rf amplifier.) A suitable cource injection circuit is shown in Fig 2 for those who may prefer it.

The oscillator circuit was borrowed from another article¹ and is conventional in design.

Adjustment

After the converter is completed, connect it to an antenna and an 80 Meter receiver. DO NOT CONNECT THE POWER SOURCE UNTIL ALL TRANSISTORS ARE IN THEIR SOCKETS. Set the bias pots, R₁ and R₂ to mid-range and place S₁ in the 20 meter position. Then adjust L₃, C₁, and C₂ for a peak in 20 meter signal strength. As the re-

Parts List

C3-Two 1-inch lengths of insulated hookup wire twisted together.

L4—Primary, 12 turn No. 20, 16 t.p.i., ¾-inch diam. (B&W 3011), Secondary, 3 turns No. 20, 16 t.p.i., ¾-inch diam. spaced 1 turn from primary.

L2—Primary, as L1, Secondary, 3½ turns insulated hookup wire wound on cold end of primary.

L3—35 turns No. 30 enam. wire, close-wound on ¼-inch

L₃—35 turns No. 30 enam. wire, close-wound on ¼-inch diam. iron-slug form (Miller 20A000RBI useable).

 L_4 -25 turns No. 30 enam. wire, close-wound on same type form as L_3 .

L5—15 turns No. 30 enam. wire, close-wound on same type form as Ls. ceiver is tuned across the band, C₁ and C₂ will have to be re-peaked every 25 kHz. or so. Place the converter in operation on 15 and 10 meters in a similar fashion. Adjust the bias pots for best converter operation, after which they may be replaced with fixed resistors or wired permanently into the circuit.

Results

The results to date have been pleasing. Although the converter has not seen much use on 10 meters, it appears to work well on that band. On 15 and 20 meters it easily

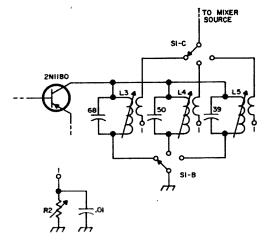

Fig. 2. Alternate circuit employing source injection. Coils L3, L4 and L5 are identical to those in Fig. 1, except that each has a three turn secondary.

CTK'S BARB'D WIRE ANTENNA

Full radiating surface but shorter than a dipole. No coils or traps to distort the radiation pattern. The design results in increased capacitance, and therefore, shorter length, for resonance. Ideal for places where a full-length dipole is too long.

The 160 m Barb'd wire antenna is only 186 feet long. The 80/75 Barb'd wire antenna is only 94 feet long. The 40 m Barb'd wire antenna is only 48 feet long. The 20 m Barb'd wire dipole and beam is only 24 feet long.

Feed with 50/75 ohm coax—no matching devices required.

Send a \$1 U.S. money order for mailing and handling of pictures and instruction sheet for building your own.

CAMP ALBERT BUTLER INVITES HAM RADIO ENHUSIASTS OF ALL AGES

TO TRY FOR YOUR

GENERAL CLASS TICKET

THIS SUMMER! OUR 8th SEASON

NOVICES, TECHNICIANS AND C.B.'ers ESPECIALLY TAKE NOTE

This co-ed Amateur Radio Camp, Y.M.C.A. owned and operated, can accommodate 60 campers. There is no age limit. We have had campers from 7 through 74 years of age. It is very helpful if you can copy 5wpm or bave a Novice or Technician ticket, but it is not necessary. Time is divided between radio classes in code and theory and the usual camp activities, such as swimming, archery, riftery, hiking, etc. Gold privileges are included at the beautiful New River Country Club course. Entire staff consists of licensed hams who are instructors in electrical engineering in some of our finest colleges and universities, Camp opens August 5 and closes August 19. Tuition of \$175.00 includes ail camp expenses: room, meals, notebooks, textbooks, and insurance. Send for our brochure.

Sealing Coaxial Cable

After a coaxial line has been hooked up to an antenna, most hams wrap it with plastic electrical tape and spray it with lacquer to waterproof the cable and protect it from the weather. This method works quite well for a little while, but after several months exposure to heat, cold, rain and our polluted atmosphere, the plastic coating and tape deteriorate quite badly. Also, if the cable flexes in the wind, the tape has a tendency to pull away from the outer jacket. If you use Silastic Bathtub Caulk instead, the line will stay dry for long per.ods of time. This material is impervious to moisture and most contaminants and is very flexible. If the cable is cleaned with soap and water before the caulk is applied, it adheres very well and is nearly impossible to remove. It retains its characteristic under all extremes of temperature and even stays quite flexible in very cold temperatures, so it won't crack and peel. I don't have any idea what the terminal life of Silastic is. but it has not deteriorated at all on cables that I installed six months ago. I already had to replace peeling and cracked tape coverings applied to other cables at the same time.

WWV on the Mohawk

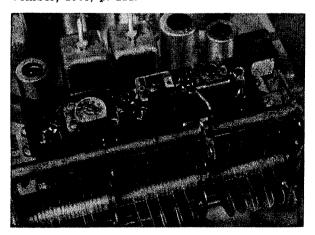

Mohawk owners who have remounted the crystal calibrator trimmer on the top of the chassis¹ may still have difficulty finding WWV at 10 MHz using the trimmers supplied with the kit. The trimmers have to be connected across the proper main tuning capacitor sections, a job further complicated by the rather small size of the trap door on the top of the cabinet. Another problem is that WWV reception on 10 MHz is unreliable under adverse propagation conditions.

A solution to the problem is a plug-in converter that allows reception of WWV at 5 MHz. Three trimmers are connected across the proper sections of the main tuning capacitor to tune the 40 meter band to 5 MHz. No modifications are made to the receiver itself.

A little investigation uncovers the fact that the stator sections of the main tuning capacitor in use on the 40 meter band are connected to three eyes in the ceramic insulators on top of the frame. These eyes are just about the right diameter to fit standard banana plugs.

The plugs are mounted on a 1½ x 4¾" piece of ¾" phenolic or Plexiglass. Drill the holes for three stud-mount banana plugs

¹ "Mohawk Tip," Giannotti, 73 Magazine, November, 1965, p. 121.

along one edge, spacing them 2" apart Mount the plugs and check the fit in the main tuning capacitor—do not use any force, the ceramic is rather fragile. You will find that the plugs are a loose fit in the holes, so carefully pry the leaves out to provide good contact and mechanical support.

The trimmer capacitors can be anything handy, but it is much easier to adjust the oscillator if a small ceramic trimmer is connected across a larger value fixed silver mica capacitor. The NPO ceramic trimmer does not drift and holds its setting even when the converter is knocking around in the desk drawer. The final setting of the oscillator capacitor was a total of 200 pF, measured on a capacitance bridge. The mixer and rf capacitances were 110 pF and 151 pF respectively. Choose your trimmers keeping these values in mind. This puts WWV on the 7.1 MHz dial calibration.

Mount the trimmers and fixed capacitors (if used) on the board and wire the unit. One side of each trimmer goes to each of the three banana plugs. The plug closest to the front panel is the oscillator, the next one is the mixer, and the last one is the rf section. Connect the other terminals together and connect a short flexible lead to this tie point. The clip is connected to the frame of the main tuning capacitor and serves as a ground return path for the three trimmers.

When the unit is complete, plug it in and tune the receiver to 7.1 MHz. If the trimmers were not preset it will be necessary to find 5 MHz. Tune a signal generator to 5 mc and adjust the oscillator trimmer until the signal is heard. Peak the mixer and rf trimmers. Now turn off the signal generator and tune for WWV. It should be nearby. Repeak the mixer and rf trimmers and the job is done. Now whenever you want to hear WWV merely tune to 7.1 MHz and plug in the converter.

High-Pass Receiving-Antenna Filters

Many of us have used a second rf stage, a preselector with tubes a passive tuned circuit ahead of a receiver, or tuned traps to eliminate unwanted signals. This has been with varying degrees of success. The traps probably have been the most effective where their single frequency does the job.

There remain some images in modern receivers, particularly at the second mixer. Also, there are spurious signals produced by one or more local broadcast stations causing a signal to appear at a false place in an amateur band. In my case, an open-wire telephone line crosses the property. It passes one broadcast station seven miles away, and two others about 18 miles away. The difference frequencies move amateur phones into the CW band. KP4CNN said that he had troubles with a transceiver, until he stopped the broadcast-station signals from going through the pi network to the grid of the first receiving tube.

In order to test rejection circuits for undesirable effects, I fed a signal generator into

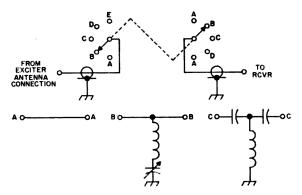

Fig. 1. A two-pole, multiple-circuit rotary switch for inserting various filters in receiving antenna line.

a cubical quad. Then I connected a receiver to a filter and to an 80-meter grounded antenna, trapped for 40 meters. Next time, I shall switch the antennas, for the long wire gave a mismatch for other frequencies, which appears to be the cause of a slight increase or decrease in receiver signal-plus-noise-tonoise ratio on 21 and 28 MHz. The quad in its simple unmatched configuration is useful for reasonably flat standing-wave ratio. However, it feeds a very wide range of frequencies into the receiver, including broadcast band, VLF and even audio (5 and 10 kHz) carrier systems. This pick-up in a quad is far greater than in a horizontal dipole or vagi with a suitable matching device.

Tuned circuits

In an attempt to improve everything at once, I tried a parallel-resonant tuned circuit mounted in a shield box. This used a link and a tap on the coil for 50-ohm input and output to the receiver and antenna. With it, the desired signals were reduced in strength and were strongest when the circuit was off resonance. This apparently corrected the standing wave reflected by the receiver toward the antenna. The rejection of off-resonance signals was not outstanding.

A pi-wound choke from the antenna lead to ground did not cause any loss of receiver sensitivity measured by SN/N ratio with and without the choke. A capacitor inserted between the choke and ground then could tune the series-resonant circuit to the broadcast band. Although this caused one broadcast station to disappear when tuned out, a station on some other frequency became louder. This also appears to be caused by the reactance of the circuit improving reception on

another frequency. Several of these traps probably could have been used to eliminate the three offending stations. This approach was not attractive because of the VLF and audio carriers on the telephone line.

High-pass filters

The next step was to insert a simple "T" high-pass filter in the antenna line, with a theoretical cut-off between the broadcast band and 3.5 MHz. Air Dux coils were tried first, using the inductance given in World Radio Laboratories' catalogs, and checked with a grid-dip oscillator. Convenient nomograms for this appear in the R.S.G.B. Data Reference Book, and in the Knightkit GDO assembly manual. Good performance also was obtained from small one-cent surplus chokes and a sack full of mica capacitors. It was convenient to include in the shield box a twopole rotary switch with a number of positions. Fig. 1 shows this, which provides connections for straight-through use for inserting a number of devices for comparison.

Filter A had one section. It was designed for a 50-ohm input and output, with a 2.6 MHz cut-off. It used two .0012 µF capacitors in series with the antenna and a 1.5 µH Air Dux coil between ground and the connection between the two capacitors. This attenuated signals a few unimportant decibels in the noisy 80-meter band, as shown in Fig. 2. This and all other filters with a cut-off below 3.5 MHz had an attentuation of 0.5 db or less at 7 MHz and at 14 MHz.

Filter B included a second section without a shield between coils, which should have been provided. The two series capacitors between sections were replaced with one capacitor of half the value. This two-section filter had no attentuation above 3.6 MHz, except for a loss of 4 dB at 21 MHz.

Filter C used a 2.5 μ H Air Dux coil, and two .0016 μ F capacitors with a cut-off of 2.0 MHz. This produced a gain in receiver SN/N ratio in most of the 80-meter band, and only a 1.0 dB loss at 21 MHz. For simplification, it is not included in the graph.

Filter D used a 2.0 µH miniature choke. This one had a large attentuation at 3.4 MHz, and gains in the mid-band region, disappearing at 4.0 MHz. It also had a slight gain of 0.5 dB at 7 MHz and 28 MHz, with a 1.0 dB loss at 21 Mc. It remains in use, although the increased rejection by a second section would be useful.

Later, in order to eliminate any signals

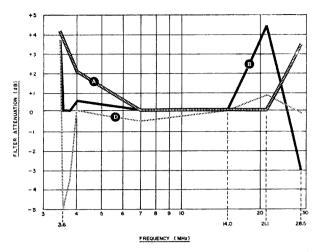

Fig. 2. Attenuation or gain measured with several high-pass filters in the receiving antenna line.

below 10.7 MHz that might beat into the 14 MHz band, another filter was built using a coil of 0.37 μ H consisting of four turns airwound on a ¾-inch diameter, with two .0003 μ F capacitors. No signal-generator measurements were made, but the S-meter indicated that there was a very slight loss at 14 MHz, and a large attentuation on the lower amateur bands.

Conclusion

No attempt was made to correct a possibly very poor standing-wave ratio for the undesired frequencies. This might be done with a resistor across each end of the high-pass filter. The impedance then presented to the filter may not deviate very widely from the design impedance. It would reduce desired signals somewhat. Without resistors, some reduction in the adverse effects upon the rejection of undesired signals by the poor match for off-frequency signals, may result from using two or more filter sections.

Lacking an all-band receiver, no attenuation measurements were made in the rejected frequency range. The filters have been used for a number of months. In a few cases, a single-section filter has brought in a weak spurious signal that was not present in the straight-through switch position. About half of the apparent commercial intruders in the 14 MHz band were weakened or eliminated by a filter, where this phenomenon was due to two signals intermodulating within the receiver. It has been interesting to find that high-pass filters were more effective than an added tuned circuit, with less loss.

Letters

Up to Data Articles

Dear 73:

Just a short comment on your excellent articles—last year I taught electronics in a high school vocational program and used many of the design and more technical subjects as teaching aids. Your topics are so up to date that I have incorporated some of the circuits I've found in 73 in the R&D laboratory at which I'm presently employed.

Edward F. Steinfeld, Jr. 7587 Roselawn Drive Mentor, Ohio 44060

73 is Stronger

Dear 78:

It seems that 73 is made from better stuff than Brand X or Brand Y. It is noticeably more difficult to drill holes in 73 than in the other mags. 73 almost stalla a 1/4 inch drill with a 1/5 inch bit . . .

Adam Denison, Jr. W4RWH Bowman Gray School of Medicine Winston-Salem, North Carolina

1967 International Mobile Rally

Dear 73:

Please announce to your readers that they are all invited to the 1967 International Mobile Rally to be held at RAF Alconbury, Huntingdonshire, England, on 18 June 1967. This rally is jointly sponsored by the United States Air Force and the Amateur Radio Mobile Society. Every effort is being made to provide truly international representation at this rally; correspondence concerning this show should be sent to the Project Officer, Mars Director AJ1AA, International Rally, Rox 3234, APO New York 09238.

George T. Martin, Jr. Capt., USAF G5ACY

Experiments with Gravity

Dear 78:

I have heard of a national group of some kind involved with amateur experimentation using gravity for communication and/or motivation. I would be very interested in how to contact someone to obtain further information.

Harold Johnson WA6DZL Box 144 La Puente, California 91747

Can anyone help Harold?

Disappointed

Dear 73:

And now you have come out with a new binding which seems to be very similar to the unmentionables. Contrary to statements it does not stay open on the bench. I cannot even keep it open while I read it. Your articles have always been good, but not really that much better than QST or CQ. If this keeps up I will enter by subscription to S-9 (for CB'ers); at least their magazine stays open.

Jay Johannes WA90HS 4235 North 68th Street Milwaukee Wisconsin

Helping Out

Dear 78:

The International Telecommunications Union, the organization established 100 years ago to regulate international communications, will be meeting in the next couple of years. To keep amateur radio and allow it to grow, we need the neutral countries; The Afro-Asian countries who have no need of our bands for propaganda purposes.

A few years back the balance of power was held by the European countries and the U.S., but now because of the one vote per country rule, it is in the hands of the new countries of Africa. This is because she has most of the new countries; we need Africa.

I have talked to many African Students, and the majority of them don't even know what amateur radio is. These are the future leaders, the sons and daughters of the ruling families. If these leading families don't know about amateur radio, we must teach them.

Why don't we start a campaign to educate these students to the good of amateur radio? We all have extra gear in our junk boxes that could be donated to this cause. Interested parties please contact me.

Bill White W3TYV 308 Gaskill Street Philadelphia, Pennsylvania 19147

All Homebrew

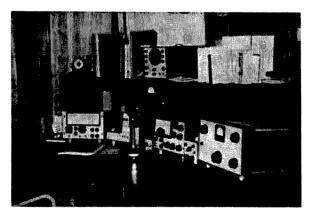

Dear 73:

Here is a photo of my homebrew amateur radio station W9DSP. This equipment is mostly solid state and has been under construction for about three years. That is to say it has been in use for the past two years with about one year of building.

It is obvious to me as a subscriber to 73 that your policy is futuristic and encompasses the solid state concept of the art. It might be enlightening to your readers to publish a picture of this solid state equipment at the amateur level; in the past two years of operating this equipment, almost invariably the station I am working exclaims to me that I am his first QSO with someone who builds, let alone all transistor circuitry. Hi.

Keep up the good work on advanced techniques in amateur radio; we need this information to survive.

> Willy Moulton W9DSP Route 4, Box 136 Chippewa Falls, Wisconsin

Left to right at W9DSP: All transistor receiver covering 3.5 to 30 HMz with room for 6 and 2 in the future; Includes FET's. Power supply and control. 125 watt DC input transmitter; all transistor except for three tubes. Includes YOX, VFO, PTI, five bands. Solid-state electronic keyer. tube-type linear with pair of 572B's and self-contained power supply. And on the shelf, an all-solid state (except CRT) scope and RTTY terminal unit.

What's New for You?

Response to this column has been fairly light so far. I think that part of the reason for this is that the name we've been using doesn't fit what we'd like the column to be. We're open to suggestions for a new name. The column is meant as a forum for short, timely notes that are of interest to technically-minded hams. We're looking for contributions from you, our readers, about new transistors and other components that you've used and found interesting. We also want notes about new surplus, technical conventions and meetings, technical nets and clubs, moonbounce skeds, and comments and corrections to 73 articles. All items will credit the contributor. Please send in your notes as soon as possible so that all 73 readers can take advantage of them. Send to Paul Franson WA1CCH, 38 Heritage Rd., Acton, Mass. 01720.

More Gain for the SB-100

Here's a simple hint from John Butrovich W6GTJ, for increasing the gain of the Heath SB-100, particularly on the 10 and 15-meter bands. It also makes the S-meter a bit s livelier. Simply reduce R-221 from 470 Ω to about 47 Ω . This increases the gain of the receiver considerably by increasing the injection voltage from the LMO to the second mixer. It also seems to improve the signal-to-noise ratio and has apparently caused no problems.

February Propagation Forecast

The symbols and forecast for the February propagation were a bit mixed up. Apparently the January forecast was inadvertantly repeated in February.

ATV Directory

Donald Levine WB2UMF, 150 DeLong Ave., Dumont, N. J. 07628, is trying to compile a list of ATV'ers all over the world. If you're interested in ham television, please send the following information to him so

that he can list you in the directory: name, call, address, phone number, equipment for ATV, and whether or not you're on the air now.

Corrections

There were several errors in the schematic for the "Silect Six Meter Converter" in the January issue:

1. There should be a connection between the oscillator tank circuit and 0.001 bypass capacitor to the supply voltage shown on the schematic; the etched circuit board showed this correctly.

2. The etched board layout shows a connection directly from the 12 volt supply to the rf stage tank coil; it should be connected through a 56k resistor as shown in the schematic.

3. The new designation for the Cambion SPC-1 coil forms is 2170-2-3 (1 to 20MHz); 2170-3-3 (20 to 50 MHz); and 2170-4-3 (50 to 200 MHz),

· . . Bob Boyd W1VXV

Phase-locked oscillator

A couple of errors crept into the "Phase-locked UHF Microwave Oscillator" on page 68 of the February issue. The polarities of CR5 and CR7 are both reversed on the schematic. Two R22's are shown on the schematic; the one referred to in the text is 500 ohms. Also, the fifth sentence in the second paragraph on page 74 should read as follows, "If the C_a and C_b used had ranges up to 7-10 pF, the frequency of your initial output should be about 600-750 MHz. When you have determined, with the power meter or receiver . . ."

UHF Multiplier

The circuit diagram in Fig. 1 on page 22 of the February issue ("An Improved Multiplier for UHF") gives the wrong pin numbers for the 6J6 oscillator-multiplier. The plates and grids are interchanged.

G. W. Cunningham WB2SRD

Kyle's Current Controller

John Derby, 1124 Hedgewood Drive, Lafayette, Ind., points out that K5JKX's simple current controller on page 96 of the December 1966 issue is a little too simple. Unless the screen regulator gets its voltage from some other source, it isn't going to work at all as he describes it. While the plate current of the 6V6 remains essentially constant,

DONATE YOUR EYES SO THAT ANOTHER MAY SEE

Great advances have been made over the past 25 years in the repair of damaged corneas, the clear substance that covers the pupils of your eyes. The only material that can be used to make these repairs comes from other eyes-those WILLED by their owners for removal within 4 hours after death, and the degree of success in these operations is astonishingly high.

Hundreds of people every year are able to see again because of these donations, but even so the availability of eye material is so limited that the majority of the over 75,000 who should have this surgery will not live long enough.

The need now is for hundreds of thousands of additional pledges to produce an ever increasing availability. A thousand pledges today may produce no material for many years. so the greater the pledge group, especially among the upper age levels, the greater the chance that many of those who need this transplantation will indeed live to see again.

Obtaining these pledges has been a project of Lions Clubs in many cities, and their members, or Doctors and Hospital Administrators. direct you to a source of pledge cards which you and your family must complete to make an eye donation valid. Here is a project for entire families. What greater gift could you give to a fellow man!

PLEASE INCLUDE YOUR ZIP CODE WHEN YOU WRITE 73.

TWO-WAY COMMUNICATION CRYSTALS

AMERICAN CRYSTAL CO. PO BOX 2366 KANSAS CITY, MO. the current through the string of NE-2's will vary inversely with R1. If they are drawing about 5 mA at 300 V, they'll draw about 100 mA at an input voltage of 750. Also, Kyle starts out with plate and screen both at 250 V, Screen reg, none!

Amperex Linear IC's

In mentioning these, we're departing from the usual policy of reporting on semiconductors recommended by readers who've used them, but they look especially interesting. Amperex calls one (TAA320) a BIFET -it's a MOSFET and conventional silicon transistor on a single chip, mounted in a 3-lead, TO-18 case. This results in a simple, low-noise, high-gain unit with very high input impedance (10 G Ω). Cost is low, too, around a couple of dollars. Another Amperex IC is the TAA310 class A preamplifier with 100 dB gain for audio use. It's cheap, too. Burstein-Applebee and Newark carry Amperex semiconductors.

Weatherproofing

Making a dependable weatherproof connection or seal can be a real challenge under certain conditions; it is even more difficult if it is needed 50 feet up a tower between the temperature extremes of 90°F above to -40° F, often conditions in Western Canada. An antenna experimenter, or anyone else for that matter, should look at the most economical weatherproof sealant I've found until now: Roof Shingle Cement, a sticky asphalt compound, available either in cans or in caulking gun cartridges. Any connection, splice or part to be sealed should be tightly wrapped with plastic tape and then covered with one or more layers of this compound. If the treated unit never (?) has to be opened, no plastic tape is needed, just make sure all cavities and holes are sealed to prevent condensation; be sure, because this stuff really sticks. After a while the outside forms a dry skin but the inside remains soft and prevents cracking of the seal. This asphalt compound does not seem to degrade coax lines or other materials; I did not notice any changes in the rf characteristics when used on baluns and loading coils. It is more easily available than any other weatherproof preparation suitable for amateur antenna use.

Climbing the Novice Ladder

Part VI: The formal code exam.

The eventful Saturday marking the formal code test for Judy and Joe dawned raw and chilly. A light mist ushering in the fall season lent further depression to the gray and gloomy atmosphere. Far from being daunted by such vagaries of nature, Judy's ill-concealed excitement allowed her to make but slight inroads into the tempting plateful of scrambled eggs her mother had prepared for breakfast. Far across town, Joe pushed his half-eaten waffle and sausage to one side with the lame excuse, "Guess I'm not very hungry this morning" which resulted in an exchange of knowing smiles between his parents.

Larry had arranged to pick up Joe, stopping by on the way to FN's place, to pick up Judy. Both kids had received their FCC application blanks during the week but without a reminder from Larry, Joe would have left his at home; the more methodical Judy had hers carefully tucked away in her purse when Larry arrived. Pulling into FN's driveway they made a quick dash for the house ducking what had now settled into what looked like a determined all-day rain, as best they could. FN met them at the door and after the usual hearty greetings said, "Well, you kids could have picked a brighter day for an exam but we'll be warm and cozy inside; Ma's got a cherry fire blazing in the living room fireplace; let's go up there and be comfortable." Hot coffee ready and waiting, did a great deal to relieve initial tensions and with the last swallow of the warming fluid FN asked, "You bring your FCC application forms? Larry told me the other day that you'd received them". "Right here Gramps" replied Judy removing hers from her purse while Joe silently retrieved his from an inner pocket. "Fine; suppose you both sit here at the table then and fill in your part . . . here's a couple of pens. I see you brought the little ABC's book Judy . . .

use the sample form in Appendix H as a guide. Larry and I will have another cup of coffee and if you hit a puzzler you can ask us about it."

The forms were simple and in a matter of just a few minutes they were ready. "Yours to Larry, Judy . . . I'll take Joe's". Both appeared to be in proper order so FN announced, "Suppose we go down below now and set up the CPO, round up some copy paper and pencils and have at it." No sooner said than done and in a few minutes FN said, "Guess we're all set now; as we have but the one CPO you'll have to work together rather than separately. I've chosen some copy from one of the military manuals; it has mixed letters and figures and some punctuation. Larry has looked it over and agrees that you shouldn't find it too difficult

... a rainy day for the exam ...

. . . the warm-up run . . .

to copy. He seems to think that I have the steadier fist, which is probably just some of his Blarney but he's asked me to do the sending. He will copy right along with you probably hoping that he can trip me on a mis-cue here and there, eh Larry?" "Don't be so modest, FN" replied Larry, "when have you ever sent a wrong character?" With a chuckle FN said, "Plenty times . . . plenty, but all right, if thats' the way you want it, remember you asked for it!" I'm going to send just a bunch of random stuff for a few minutes to give you kids a chance to get the shakes out of your writin' hands . . . kind of a 'warm up' run. Copy what you can but remember, if you're doubtful about a character don't hesitate to puzzle over it . . . Just skip it and go right on." With that FN commenced with the attention sign and continued in a slow, steady rythm, sending sentences from the book in front of him. Joe and Judy industriously copied with complete concentration for what seemed an interminably long time. At last FN wound up with a flourishing 'SK' and the two kids laid down their pencils with long, relieved sighs. "Well, how'd you do?" came from FN. "I dunno Gramps," said Judy; "for the first minute or so it seemed like a bunch of jibberish to me but then I began to catch on and it came a lot easier; maybe I didn't do too bad". "let's see" said FN, reaching for her paper and passing it to Larry with, "You look it over Larry, I'll see what Joe did with it". Taking Joe's copy, FN checked it character for character with the copy from which he'd been sending, then passed the book to Larry who in turn re-checked Judy's effort. "Looks pretty good here FN" and unseen by either youngster, Larry slipped a sly wink toward FN who acknowledged with a slight nod. "Now" said FN, "before you kids do any more copying, suppose you take a little break from the pencil and limber up your wrists on the key; you'll have to send as well as receive you know and you don't want to be stiff. Iudy, suppose you send this short paragraph for a warm-up session; we'll all copy . . . you too, Joe . . . and see what you can do." Judy took the book and starting where FN had indicated steadily plugged along to the end of the paragraph. "Now Joe", FN said, "take the next paragraph and Judy you copy him this time along with Larry and me." When Joe had completed his run, FN carefully checked against the book and then mystified both of the kids by exchanging broad grins with Larry. This was immediately explained though when FN said, "Congratulations; you have both passed your sending and receiving tests with a good safety margin . . . nice goin." "How come," Joe said . . . "was that the exam?". Laughingly FN replied, "It sure was Joe; a little psychological trick I picked up long ago when I first commenced to examine novices. Almost invariably they'll be much less tense and at greater ease if they don't know they are being formally examined and think it's just a 'practice run'; had you fooled didn't we? Larry and I had this all fixed up beforehand and you walked right into our little trap and obviously to your advantage. Here's the results; we had already counted characters in the material you sent and received so it was possible to quickly gauge what you did when you finished. Joe, in your receiving test, you came up with five errors in the five minute run; in four cases it was that same old letter Y that has been plaguing you. The other error was that of omission; you apparently missed a character, let it go and went on with your copy, as you should. However, three times in the five minutes you copied 25 or more characters solid; any one of these solid copy stretches would have passed you. You got a little added break in one run; it contained three figures and a punctuation mark; remember, these all count as two characters in the final score but even without that bonus, you made it; very good lad. Now Larry, what did you find in Judy's

98 73 MAGAZINE

copy?". "Error-wise, she did better than Joe, FN; Judy you chalked up only three errors but they occurred at points which left you, like Ioe, with three complete 25 character strings, more than ample to pass you. Two of your errors were in figures so that cost you four characters really, plus the other one which was copying an 'x' for a 'y' and counted as a single error, so you and Joe were actually just about even. FN, what did you figure your sending speed to be?" "I tried to hold it as close to 5wpm as I could judge Larry," replied FN, "but maybe force of habit sneaked it up a bit on me for I was actually sending at an average speed of slightly over 6wpm . . . say about 64, so if either of the kids had failed, I'd have had to run it over and bring my speed down to exactly five". Beaming faces and broad smiles from both kids greeted these remarks and then Judy chimed in with an eager question. "How about our sending then; tell us about that". Nodding to Larry, FN said, "Go ahead Larry and give Judy an analysis of what you think of her fist".

"Well Judy, I'm going to give you a baby Oscar on that one; you've developed a nice, clean steady fist and your character formation is excellent as I think FN will agree. I clocked you at just slightly over 6wpm . . . perhaps FN's sending cued you in at that speed. More than you needed but even better so. You made only two errors in the entire five minute run; one was in adding an extra dot to the figure 7, the other was in making a period where it should have been a comma. Now let's see what FN's got on Joe. "This time I'm going to give Judy the edge on Joe," FN said, "remember, I copied both of them. Judy's sending was steadier than Joe's. It was evident that he was crowding himself a bit for speed. You came out at exactly 7½wpm Joe, probably through a sub-conscious feeling that maybe you weren't quite making your required five. As a result, your sending was a bit jerky; you'd have made better characters and fewer errors had you held down to 5 or 6wpm, however you made readable copy in two runs of better than 25 characters each which, of course, passes you. You made seven errors scattered throughout; here's your paper-I've marked the mistakes and you can check them against the book." While Joe was checking his copy, Larry gathered up the miscellaneous papers while Judy's relief was evident in her completely relaxed slouch in her chair. "I'm wondering

about something," said FN, "in this past week you kids have both taken a rather sudden spurt in cour copying speed-you been practicing together a lot this week?" "None" Judy replied, "Joe phoned me and said that Larry had shown him where to find the code practice transmissions on the amateur bands and he told me where to look for them. So, we both tuned 'em in on every schedule we could possibly make. That sure helped-thev came through on both of our receivers just like we were in the room with a CPO. A little ORM at times but plenty of good solid practice. Boy, I'm really sold on copying actual signals-makes you concentrate a lot harder, doesn't it Joe?" "Right" returned Joe, "I sure got in a lot of good licks with my old BC-312". "Swell," came from FN, "stay right with it-you're going to be shooting now for the 13 wpm you'll need for your General class exam within the year and you'll get a lot of help from the CP stations. Don't relp too much on copying other hams at random, particularly the novice group. You'll find all kinds of fists, good and bad but the CP stations practically all use automatic tape transmissions which is perfect character formation and that's the type of transmission you'll have to copy at the FCC office when you take your General exam. Well, we've got about an hour before lunch time; do you want to talk about transmitters for a bit? If you pass your written tests you know, you're free to get on the air the minute you receive your license and call letters from FCC; be a good idea to start thinking about what you're goin' to use for transmitters". Eagerly Ioe said. "Gee FN, I'd sure like to start doing something about a rig; I'd like to get on the air just as soon as I get my license". "Me too," Judy chimed in. "I'm getting kinda anxious to talk back to some of these stations I'm hearing all the time. My little CONAR receiver is sure hauling 'em in and I'm getting so I can read quite a bit of what they're saying".

"All right" said FN, "let's see what we can do about it. There are several ways in which you can acquire a proper transmitter for your novice operation and, if you plan right, it can be a piece of equipment which you can carry right over into your General class activity when you reach that stage. First off, is the 'home-brew' approach. While I'm a great believer in the ham building as much of his equipment as possible, I'm going to discourage this angle for you kids. Here's

why; you can build a very satisfactory little rig from scratch by following one of the many designs for simple rigs in any of the handbooks or from one of the magazine articles. Sometimes, this is the least costly approach moneywise although the time element for such construction will penalize you a bit. Ordinarily, like you kids, the novice will have little in the way of a 'junk-box' which hams call the miscellaneous accumulation of parts and components which they inevitably gather as their ham career progresses. The amateur with a couple of years or so of ham background can generally pull about 50% or more of what he'll need to build a piece of gear, right out of his junk box collection. However, if practically everything you'll need to put together a novice transmitter must be purchased new, money saving is a bit questionable. On top of that, the relative inexperience of the novice hardly lends itself to producing a really presentable job particularly if he is unequipped with such convenient tools as socket punches, hand or electric drill, nut-drivers, soldering iron and similar items. To have to buy these in addition to parts runs the cost figure to a pretty substantial sum. In my opinion, the novice is really better off to take another approach and defer the major home-brew construction until he is a little better equipped all ways. And what other approach do I recommend? There are several; let's examine them.

"You can buy a brand new, factory assembled and wired transmitter, ready to go. There again, you're going to face a rather substantial cost item. And, by so doing, you won't learn anything about electronic construction; just adjustment and operation. The older hams term this approach being an appliance operator'-just a button pusher and knob-twirler' as it were. Later on in your ham career, after building a number of pieces of equipment, you can think seriously about buying some good factory-built job. You'll find then that through the experience gained in building a few items from scratch, you can handle a commercially built job much more effectively through a better understanding of the functioning of the various components.

"Another approach is to buy a good, used transmitter if of a reliable make, free of modifications and including the factory instruction book; this latter is important both for operation and maintenance. Here again

The novice transmitter . . . to buy or build, kit or surplus, homebrew or factory assembled?

however, you gain little in furthering your knowledge of electronic construction but you will effect quite a substantial saving over the cost of a new piece of gear. Then too, there are always the kits and they are far from a poor bet for the novice. In addition to being priced considerably below a factory completed job, they do give you a certain amount of assembly and wiring experience which you won't get on a complete factory built job. Too, the really hard work is done for you such as holes punched and drilled in chassis and panel, panel lettering applied and many little niceties accomplished for which you would require a rather impressive list of special tools; pliers, screw driver and a soldering iron just about cover the major tool requirements for putting together a kit.

"Personally, I favor for the novice, either buying a new kit of reliable manufacture or, as second choice, a good used transmitter of well-known national make. Both of you kids have catalogs of the leading kit makers, Knight-Kit, Heathkit, Johnson and others. I'm going to suggest that you go through these carefully and see what you can find that is suitable for novice operation and priced within your budget. While you're

thinking these over, make another round of our three local electronics stores and see what they may have on their used equipment shelves. In general, it is better that you avoid a piece of surplus military gear; there are lots of good items among them but ordinarily they are not completely adapted to novice operation without considerable modification which, while relatively simple for the experienced ham is usually a little bit rougher than beginner should tackle.

"Suppose then, you do as I suggest; study your catalogs and visit the stores. When you think you've come up with something that looks like it might fit your picture, come on out and we'll talk about it. Meanwhile, don't forget that while you've satisfactorily passed your code tests, you still have the written examination ahead so keep right on boning in the little books . . . you'd hate to think you'd made the code and then flopped the written

portion, wouldn't you?

Assuring FN that they most certainly would keep on with their study, they agreed to his suggestions and as lunch time was fast approaching, all three loaded into Larry's 'Gallopin' Gertie' for the homeward trek shouting their "73" to FN as they drove off. . . . W70E

Hand Buffer

Some of the homebrew specials look a bit rough at times due to the use of heavily tarnished surplus connectors. The average amateur has no means for cleaning them easily and soaking in any kind of solvent does more harm than good. Many connectors, materials and other parts are often very fragile and impossible to clean with sandpaper or solvent. One of the best and easiest ways of cleaning these things after trying everything else is by using a so-called "suede leather brush" as a hand buffer. This is a small brush made with copper clad steel wire and intended for cleaning and sprucing up suede leather shoes. These brushes can be real life savers to a home builder and work wonders on tarnished silverplated rf connectors and similar parts. They are also a great help in cleaning a plated chassis without scratching it, cleaning files, etc. At 25-30 cents these brushes are a real buy.

Heathkit HW-32A 20 Meter SSB Transceiver

When Heathkit brought out their single-band transceivers a little over three years ago, they immediately became very popular. They were low in cost, versatile, compact and ideal for the ham who wanted to move up to SSB with a minimum of effort. Now the people out in Benton Harbor have gone one better—they have introduced a new set of single-banders with even more features than the original.

These new single-banders feature upper and lower sideband selection on all models, improved audio and AVC response, automatic level control (ALC) input for external linear amplifiers and improved design and styling. The nicest feature of all is that all these additions are available at no additional cost. In fact, the price is even lower than the original models. With prices increasing everywhere, it's refreshing to see a new piece of amateur equipment offered with a lower price tag.

Heath's famous quality is evident throughout the entire HW-12A, 22A and 32A line. This borne out in on-the-air performance; both the receiver and transmitter have been designed for optimum SSB performance and show it. The 1 μ V sensitivity, 2.7 kHz selectivity and slow AVC action make for very enjoyable SSB operation. The 200 watt PEP of the single-banders isn't going to crack any DX pileups, but all continents can be worked without a great deal of effort. In only a couple of days of part-time operation WAC was made from W1DTY with excellent reports.

For the ham who wants to work mobile, the HW- series is really the ticket. Mobile performance with the HP-13 DC power supply is excellent. A mobile mount is supplied with every unit and the front-panel bias control speeds up conversion from fixed station to mobile use.

In the receiver, the pentode section of a

6EA8 is used as an rf amplifier. The triode section mixes the input signal with the VFO to provide an output at the 2304 kHz if. This combination results in a sensitivity of 1 μV for a 15 dB signal-plus-noise to noise ratio.

The four-crystal crystal filter following the mixer exhibits 2.7 kHz selectivity at the 6 dB points and 6 kHz selectivity at 50 dB down. Two 6AU6 if amplifiers, a 12AT7 product dectector and a 6EB8 audio amplifier and power stage complete the tube lineup in the receiver.

A 6EA8 microphone amplifier and cathode follower in the transmitter drive a diode type balanced modulator. The output of the balanced modulator is amplified by a 6EA8 transmitting if amplifier before the signal is fed into the crystal filter. From the crystal filter the signal is amplified by another if amplifier, a 6AU6, and then mixed with the VFO signal in a 6EA8 mixer stage. In the final a 12BY7 driver stage pushes a pair of 6GE5's to 200 watts PEP input.

The Heath single-band transceivers may be switched from transmit to receive by either push-to-talk or the built-in VOX circuitry. The 6AU6 VOX amplifier is normally operated in a saturated condition, but when audio is applied to the grid, the plate voltage rises and fires a neon bulb, providing positive switching action. The voltage from the NE-2 neon is amplified by the relay amplifier, the triode section of a 6EA8, which operates the transmit/receive relay. The builtin antitrip circuitry and VOX delay result in very smooth VOX operation. The VOX delay and VOX sensitivity controls are located on the rear panel where they are easily accessible during initial VOX adjustments; after that they may be virtually forgotten.

A 6AU6 is used in a Colpitts type VFO circuit and the stability characteristics are excellent. The circuit is completely temperature compensated and after a warmup of 30 minutes, the drift is less than 200 Hz per hour. To a large degree, the stability and drift characteristics of this VFO are directly attributable to its relatively low frequency of operation—1618.3 to 1771.7 kHz. The VFO output is mixed with the output from a crystal controlled heterodyne oscillator to obtain the required mixing signal for 20 meter operation.

The back-lighted dial is very smooth much smoother than some transceivers I have used costing several times as much The

two kHz dial calibration is very convenient and when used with the optional crystal calibrator, you know exactly where you're operating without a lot of interpolation. In these new single-banders the crystal calibrator socket is built in and the calibrator is controlled from the front panel-all you have to do is build the calibrator.

Construction of the HW-series single-banders is simplified by the use of a printed circuit board and a factory-prepared wiring harness. In fact, over 90% of the components are mounted on the printed circuit board. With this type of construction, assembly time is drastically reduced and wiring errors are almost non-existent. With the extensive directions and pictorial layouts provided in assembly manual, wiring smoothly and rapidly. Even the alignment is no problem-all you need is a broadcast receiver, a VTVM with an rf probe and a

dummy load. All the tuned circuits are prealigned at Benton Harbor, so it only takes a few minutes to get everything tweeked up.

Operating voltage for these transceivers are furnished by an external supply—either the HP-23 for fixed station use from 117 volt lines or the HP-13 for mobile use. The supplies are wired internally so they may be turned on and off with the function switch located on the front panel of the transceiver. The filament wiring is a series-parallel arrangement which balances the filament voltage without power-robbing dropping resistors.

I have used the HW-32A on 20 meters for several months now, and the audio and carrier suppression reports are always excellent. During a recent DX test the HW-32A with a linear amplifier added a couple of new countries to my WTW list. Whether you are an AM'er still procrastinating against SSB or are simply looking for a new mobile rig, the Heathkit HW- single-band transceivers are the most economical units available. They are dependable, compact and versatile—a tremendous value on today's market

Mobile Mike Holder

Many times the new owner of a mobile mike finds himself without a mike holder. If you are in this predicament, and your mike is the type with the button mounting as used by Shure and others, here is a possible solution.

The only material required will be a short length of rectangular extruded aluminum (or waveguide). This is available in many different sizes and most metal supply houses and surplus metal stores will be able to furnish the extrusion. The dimensions are not at all critical. A recommended stock size would be ½ x 1 with a .125 wall thickness. The maximum length required is 4".

On one side of the extrusion drill and file a ½" wide slot that will accommodate the button hangar on the rear of the mike. The slot should be about 2-3" long. On the opposite side drill clearance holes for two sheet metal screws that will be used to secure the holder to the automobile.

The appearance may be enhanced by anodizing or painting.

. . . Larry Kinner K6VNT

Proper Terminology

If you want to become known as an expert in any field, and this is particularly true of ham radio, there is no substitute for knowing and using the proper technical language. Obviously, it's more difficult to impress friends and acquaintances if they have no trouble understanding what you're talking about.

To help you overcome this problem, the following easily understood words and phrases are translated into terms calculated to make you stand out as an authority. Thus,

Don't say

The proper term is

It has a handle

The darned thing won't work I made a lucky guess

I poured the coal to it

I don't know why the circuit works My gear is the most This gear is the ultiexpensive on the market

I cut and tried until The problem was it worked

It won't work

The whole dammed thing blew up

Lucked out

The unit is portable even if it weighs 500 lb

It needs refinement

It was a matter of interpolation

I worked to maximum operating parameters

It's a sophisticated circuit

mate in precision equipment

solved by empirical means

There are technical problems

This ranges from temporary setback to catastrophic failure

Persistent effort resulted in phenomenal success

Now that you see how the process works, you can easily add many more terms to your vocabulary. A word of warning, though, be sure you're not talking to someone else almost as smart as you are. You won't know who's doing the snow job-I mean giving the technical explanation.

. . . Alton Glazier K6ZFV

MORE TALK POWER

WITHOUT DISTORTION

SPEECH COMPRESSOR CSPII

A New and novel design provides instantaneous peak limiting with no distortion. The unit installs in microphone leads and provides an effective **average** power gain of 10 dB relative to the peak output. Its usefulness applies to all forms of voice transmissions including and especially single sideband.

Gus!

Part 23

This trip from Burundi to Kigoma was a real hair raising experience let me tell you. Over swinging bridges, over very deep gorges, very bad roads, and no road signs at all. A great many animals were seen that night, leopards, lions, even three gorillas, many, many hyenas and countless other animals, many of them I don't even know the name of. Some even John said he had never seen before and mind you he had been down there for a number of years. The road was just about as bad as the Bhutan/ Thimphu road which many of you have seen my color slides of. We took off with plenty of spare gasoline, oil, water, a few sandwiches, and two thermos bottles of coffee, all of which was consumed on the trip to Kigoma. This was by far the worst part of Africa I have ever seen, before or after, its real "wild country", very primative natives, some half dressed some not dressed at all. The men-folk were all painted with no smiles from any of them either. It was one of those trips that really gives a car a good going over. Luckily we had no car trouble. I forget the exact mileage between the two places. As near as I remember it was something like 125 miles, and it took us until the next afternoon to get there, some 15 hours to drive 125 miles-that's mighty slow progress but it was the best we could do on that primative road. Things down there are run very odd. The first thing you do when you get to any village, town or city you check with the police, even if you are only going to be there a few minutes or hours. The fact that I was going to leave almost immediately had nothing to do with this formality. To the police we went. After a long wait we finally were ushered into the chief's office. He was of course a native, wanting to know why we were there, where were we going, etc. After

talking to him and filling out half a dozen forms we were permitted to depart. He told us we were permitted to stay there only two hours! These people down there like to throw their authority around when they have a chance, and this fellow was no exception. He let you know this from the time we entered his office until we departed (Gladly too!). We headed straight for the railway station, stopping at a market place on the way. I bought a big bunch of very large bananas for 47c to eat on the train (they lasted all the way to Johannesburg, South Africa). Funny thing tho, I still love bananas. After buying the bananas, I tried taking a few pictures of the market place, and boy this caused quite a rucus, let me tell you. One well-dressed fellow (a native), yelled something at me and John in their native tongue and people started coming our way, with very mean looks on their faces, John said get in the car and I did and away we QSYed very QRQ. You don't have to understand peoples' language to know when they are mad-and this fellow was-MAD-. Boy you very soon learn certain things down there, and picture taking without their permission is one thing to not do. They want some shillings for this permission. Anyway we got to the railway station and I mean by the time we stood in line with all those other natives I guess I had absorbed some of the prevailing smells. With my ticket in my hand we headed for my cabin on the train. I mean to tell you I just got settled and away the train departed. I am one of these fellows who hate to be late, but this time we could only blame that chief of police for delaying us so long in his office and his waiting room. These people absolutely will not be rushed. Don't lose your time trying to make them speed up. In fact I dare say that's when they actually slow up. You just grit your teeth

and bear with the situation, and try to figure some other way you will do it the next time. John jumped off the train, saying, "See you from Bouvet Is." or something like that and the train headed away from Kigoma towards Dar-es-Salaam. I started off the trip by eating one of those bananas. and saying to myself, Gus, you asked for it and here it is. You wanted to see Deep Africa. Well you are seeing it and HOW. There was no air conditioning on this train and there were no first class reservations, etc. You just mingled with the natives. If you don't like it just GET OFF, the only other way is to WALK. No busses, airlines, no roads. It's that train or walk. I was headed for a place called Itigi in central Tanganyika where I were going to catch an African bus to take me in the direction of South Africa. The trip to Itigi took all night, and about 4 PM the next day we arrived there. I was smutty, smelly, tired, and probably looked like the other natives by this time, and I just did not give a hurrah either. I wanted to, let's say, "go native", and that's what I had become, or at least that's how I felt about this time. Off the train and to the bus station I headed with all my gear and about three bearers loaded up. I watched them all the way. I could not afford for anything to be missing when I got to Bouvet. Things have a very bad habit of disappearing when you travel like I was doing, and each piece of my luggage was just like a chain. It's no good if one single item is missing. If it is you are stopped cold in your tracks. I did not want this to happen to me, that's why I always stuck very close to my gear. As is usual in these parts, the bus was late. In fact it was what you might say VERY LATE. The bus I was taking was from Nairobi. It arrived about two hours late. I had my bus ticket all ready and when it arrived and I saw all those people waiting for that bus, I made up my mind that I was going to be one of the passengers on it. I had all my bearers standing by with my luggage and had been instructed what to do. When the bus stopped they immediately piled my stuff on top of it, I handed the bus driver a tip and then my ticket, he motioned me into the very front seat. About half of those waiting were left behind and the bus was crammed full with not even room for anyone else to stand. Remember there are no paved roads in these parts of

Africa, at least when I was there they were not paved, and I doubt they are right now. The roads is what you might say "like a washboard" and the bus driver drove at the EXACT SPEED to make each washboard groove felt. I kept thinking of my poor equipment on top of that bus, bouncing around and numerous loose connections developing to cause me headaches later on. The top of this bus was really loaded up. Bicvcles, boxes, radio gear, chickens, and many bags containing Lord knows what. Oh yes I brought my bananas along with me from the train. About this time I ate two of them to sort of get my mind at ease. After a while you get thirsty you know, now where do you get water from? The bus finally stopped to unload a few and take on a few more passengers, every one headed for a well with a rusty bucket and drew up water that was vellow looking, and it even had a sort of evil smell to me. I had saved a paper cup from the Itigi railway station and filled it full of this roughlooking water and drew out one of my "water purifier pills" and dropped it in, after shaking it a while the pill dissolved and down my throat it went. About all I can remember about it was it was wet. warm, nasty but at least it was water. Natives flagged down the bus along the way and by pushing and shoving once in a while one more could get in. If I had been blind I could have told vou I was in Africa. Everyone was washed down with sweat, dirt, and lots of clothing I am sure had never been washed. After a while you get to the point where you just don't smell anything at all. I suppose I sort of smelled like them at this time. I was treated with respect all the way, they gave me a whole seat, even when the bus was loaded down with only standing room. The bus traveled all day and stopped at sundown at one of the "tourist huts" along the way. It cost me one dollar to spend the night at these places. They served you a cup of tea when you arrived and in the morning they would wake you up in time for the bus and gave you another cup of tea. Fairly good beds with mosquito netting on it were to be found at each of these places. The bus would usually come and get me first than go past the little bus station and pick up the other passengers who had been sleeping on the ground around the bus station. At lunch time the bus usually took me past one of

the tea rooms along the way where a fairly good dinner could be had at a fair price. This was the only good meal I would have each day. During the late afternoon you know a feller gets hungry. I finally got to the point where I would down those dried salted little fish and dried salted other meat along with the natives. It did not give me any trouble that I know of. This is one time that I "went native". I remember we stopped one day at a roadside tearoom in Northern Rhodesia. The temperature was around 110 degrees, and this tea room had a sign outside reading, "Admitted only with tie and coat". In I walked in my shorts, only a white (it was white one time anyway) shirt. They "ordered me out". I tried to explain that the temperature was 110 degrees and was too hot to be wearing a coat and necktie, that all my clothing was on top of the bus and that I was hungry and wanted some food! This did no good whatsoever, and I ended up not getting anything from that place. Back I went along with the natives and ate along with them some more dried fish and that OTHER dried meat, some very hard bread, very dark and dirty looking stuff. I knew how it was to be not admitted in a high class place. I even tried offering them double prices to let me eat there. I DID NOT LIKE THIS TREAT-MENT AT ALL I must say. For over three or four days I did not see a white face. I was seeing Africa the hard way, this I must admit. At every country border the bus stopped and we all went in the little Custom House and always the questions were about the same. Did I have any firearms, did I have any ammunition, did I have any alcoholic drinks, did I have any tape recorders, did I have any TRANSISTOR RADIOS. My answer was of course NO to all these questions. At no one single check point was my baggage opened and inspected. All that radio equipment went all the way from Tanganyaki to Johanesburg, South Africa without once being opened! I guess they figured anyone traveling on an African bus could not have anything of value along with them. My first stop was with Shorty, VQ2EW (I think that's his call). with his nice wife. Shorty had plenty of cold Cokes in his Fridge (as they call it). I understand that Shorty and his wife are now back in ZS6 land where he was originally from. He drove me all around showing me the native quarters, market place, and I met

many of his friends there. Shorty and his wife were very wonderful hosts to me. I installed my equipment on his operating table and had many a fine QSO with my friends in the USA and other countries. I told them about the proposed trip to Bouvet and Tristan da Cunha and Gough Islands. Shorty had a fine Quad installed and boy it brought in the results with my rig connected to it. The SWR was quite high, about three or four to one as near as I remember, with no noticeable ill effects as far as I could tell. These fellows down there have some mighty fine openings to the USA. You should hear those S-9+++ sigs pouring through, hour after hour down there. I wish those same fellows would come through like that over here. I used to listen across the bands doing a little eave dropping on the fellows. Sometimes I would hear someone say, "I wonder where Gus is right now" and I would call them and say I am right here, "what can I do for you?" This kinda shook them up I suppose. But it was lots of fun. I got caught up on my eating at Shorty's home but time to depart arrived and away I was again, heading for Johanesburg on that African bus. It was the same old thing all over again only MORE SO! We passed the tremendous Zambazi Falls which to me looked a lot larger and more rugged than Niagara Falls ever looked. It was late in the afternoon when we stopped there and too late to take any pictures. I did take a few but none of them turned out on account of not enough light. We went through Southern Rhodesia and then through a portion of Bechuanaland (ZS9) without any stops except to eat. I had no chance to try to get a "operating permit" there on account of the tight schedule to get to Capetown for that Bouvet island boat trip. Bechuanaland was a very miserable looking spot, at least the portion we traveled through. After it came South Africa. It was the most dramatic change of scenery I have ever seen. It was like moving from Africa of the 1800's to modern-day America. Right at the border the rough washboard, unpaved road changed to a big wide asphalt highway. It sort of reminded me of half of the New Jersey Turnpike. Later on I found this type of road was to be found practically all over South Africa. That's it for this month fellows. BOUVET HERE I COME.

. . . Gus

EDDYSTONE

GEARED SLOW MOTION DRIVE FOR AMATEUR RADIO & COMMUNICATIONS RECEIVERS & TRANSMITTERS

A high grade assembly designed for receiver and instrument applications. The movement, manufactured to fine tolerances, is free from backlash, gear-driven and flywheel loaded, giving a smooth, positive drive, with a reduction ratio of 110 to 1. The vernier, marked 100°, rotates 5 times for one pointer traverse, giving 500 divisions with positive reset readings. A cam adjustment on the vernier assures correct zero setting. A spring loaded jockey arm maintains tension of the pointer drive. Overall dimensions 9-3/16" x 5-3/4".

teurs working for the overall benefit of our group of hobbies. Well, damned few.

The idea seems to be let George do it. Well, there isn't any George.

Techs on Ten?

Still another letter asking why not Techs on ten meters. The complaint is that the Tech doesn't have any code practice available up on six meters and that when someone does try to send some code he gets cat calls from other Techs.

I never heard so much clap trap in my life. Any Tech . . . or anyone else . . . that wants to learn the code can do it the way most of us have done: sit down and copy it. You don't need a transmitter or even a license to learn the code. All you need is a receiver and enough gumption to sit there for a few days writing down all the tripe you can decipher until you can read it at thirteen per.

DXpeditions

Sometimes I wonder how DXing was thirty years ago, just before I came into ham radio, before the ARRL DXCC and Honor Roll came into being. I wonder if DX operators were hounded right off the air from every relatively rare spot by the QSL head hunters? I wonder if the great bulk of the DX contacts in those days were for the purpose of getting a QSL or were perchance for the joy of the contact itself?

Now that I've operated from dozens of countries around the world I realize that a kilowatt transceiver, a three element beam up 70 feet and a few days just for hamming will give me DXCC from anywhere in the world. And if I don't have to spend too much time working I can get up in the 300 plus country list in a year. I don't need much in the way of brains, though they help, obviously, or even any technical knowledge, just persistance.

Having DXpeditioned myself a bit and being on excellent terms with many of the top DXpeditioners, I don't want anyone to think that I am intending to be in any way critical of the chaps who put on DXpeditions. But . . .BUT. . . DXpeditions have brought on a very dangerous situation and, unless some major changes can be made in

MODEL 400 AND 501

TV CAMERAS

From \$125.00

Each month we have a limited quantity of used TV cameras which we make available to hams at greatly reduced prices. Some cameras were used as demonstrators by our salesmen; others like our Model 400 were traded in for our 501. A few are back from being rented out on special temporary surveillance jobs. Some were modified slightly to fit the particular job and may have extra holes or vary slightly in appearance from the photos. All have been checked out and are guaranteed for 90 days. Complete with vidicon and lens.

Model 400 sale price \$125.00 FOB Hollis Model 501 sale price \$160.00 FOB Hollis

These used cameras are for sale to radio amateurs only. Include call letters with your order.

DON'T DELAY. ONLY A FEW ARE AVAILABLE EACH MONTH.

For specifications on the 501 see our other ad elsewhere in this issue. For specifications on the 400 see 1965 issues of 73.

VANGUARD LABS

196-23 Jamaica Ave. Hollis, N. Y. 11423 the DXCC rules, my present thinking is that all of us should do as little as we can to encourage them.

Whoa, don't jump to any conclusions. Not one of you reading this even have an inkling of what I am about to say, save perhaps the chosen few of you who have had the privilege of visiting some of the rarer countries and are familiar with their political problems.

Here and there around the world I've visited places or received letters from spots where a DXpedition has left some ruffied feelings. This happens, of course, but it is relatively rare and seldom does this result in any serious repercussions to local or following amateurs.

The real problem is this: in several countries around the world amateur radio is tacitly permitted, only don't ask for a license. A visiting amateur goes to the licensing authorities and is given a shrug. Go ahead and operate, but please don't ask me to sign anything because if there is any trouble I don't want the responsibility. It's like our own State Department, no one wants to be responsible.

All goes well. Our visitor goes on the air, contacts a few thousand stations, makes everyone happy, and departs for greener pastures. Then, sometime later, comes the bomb. A letter comes to the government from the ARRL asking if the amateur had a license. The letter stirs up a hornet's nest and the Minister of Communications, if he doesn't lose his job or even his head, is going to be mighty careful about saying yes to the next ham visitor.

The ARRL has decided, for some reason, that it is up to them in some cases to determine the validity of a DXpeditioners license. This, unfortunately, can cause grave international complications. And we certainly don't need any such problems right at our present time in history where we are waiting to see whether the countries of the world are going to get together and take our bands away from us. Right now we should be doing everything in our power to prove the value of amateur radio to the small countries of the world, not causing serious internal political complications through base stupidity.

Well, at any rate, since there is little possibility that the League is going to stop meddling with foreign governments, perhaps we should try to work from the other end of the street and do what we can to discourage DXpeditions from now on. This is simple, just stop sending those generous donations which are supporting the DXpeditioners. When the money stops the DXpeditions will stop. This is lot easier to stop than the ARRL and may be the better solution. The next time you reach for your checkbook just remember that you may be doing a lot more harm than good to amateur radio.

Public Relations

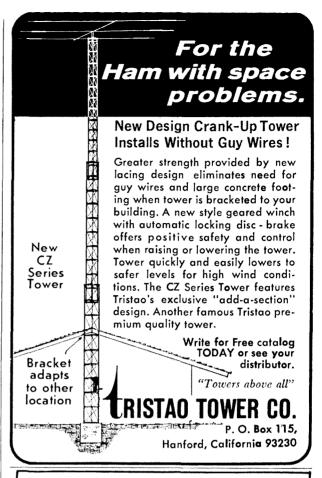

The number of licensed amateurs dropped by about 5% last year, the FCC has reported. Things slowed down coincident with the ARRL announcement of RM-499 and Docket 15928, the official outcome of 499, is coincident with the unparalleled loss of interest in our hobby.

What's done is done. We can hope that it won't happen again. The board of the ARRL moved last May to prevent something like this from surprising us by requiring that the ARRL executive committee check with the board of directors in the future before sending any further earth shaking petitions to the FCC. It's too bad that barn door wasn't closed before RM-499. The executive committee cooked up 499 and sent it along in without consulting the members or, apparently, even the full board of directors.

So, at a time in history when it would be most prudent for us to be fruitful and multiply we find that our ranks are thinning. We need strength today to hold our amateur bands. This means that continued growth is basic to our survival. Unfortunately there is little being done to promote our growth. Here we are, plunging into the electronic era, and the leading scientific hobby is withering away faster than it grew a few years ago. With over half of the population of our country under 21 we should be experiencing a record growth, with radio clubs starting in high schools all over the country.

What is the problem? You know as well as I. No publicity. Or at least very little publicity and no organized promotion at all. We should be making sure that the youngsters are made well aware of amateur radio and we should get cracking on this or we will be in deep trouble.

How can we get the word out? Lordy, we have one of the most interesting hobbies ever invented . . . all we have to do is just tell people about it. Right now we're not doing this. This is not a job for one man or even one radio club, it is the job of a large

organization, one that is geared to handle something of this size.

The ARRL could, if it wanted to, reverse the tide. And it could do it this year. By increasing the membership dues by 50c per year or by increasing their advertising rates in QST by a mere 10% they could have a whopping fund to hire a good public relations firm which would make sure that the entire country knew about amateur radio is short order. We would be having articles on our hobby in all of the major magazines regularly . . . Look, Life, Post, Boy's Life, True, Playboy . . . and on down the line. A PR firm could coordinate the writing of articles and get them into magazines, newspapers and even on television.

Perhaps it is time you phoned your director and bugged him to get this going and going right now. We can't wait until 1968. This is not the time for a study or a committee, it is time for PR. The directors meet only once a year, in May, this month, so if they don't get this through right now they won't even have a chance until a year from now to start on it.

I can't go into all of the details here without writing a large book, but I think I can give a good answer to any possible argument that can be brought up opposing ham PR. For instance, should anyone suggest that the raising of membership dues by 50c will be catastrophic you might ask them if they are aware of the dues that most other national organizations charge club members. If you belong to any other clubs you know that most of them are \$10 to \$15 or so a year and this usually includes a smaller magazine than QST. And QST's advertising rates are about one third to one fourth those of any other magazine comparable in another field, so they could easily increase these rates anytime they felt any need for extra money.

It won't hurt a bit to talk up the PR thing on the air and get as many fellows as possible to call their director. There is no time to lose. Unfortunately most directors are "too busy" to get on the air so you'll have to use the land line.

In addition to the top notch writers in our ham ranks such as Jean Shepherd (K2ORS), the most published author in Playboy and winner for two years running of their coveted award for the best story of the year, we have the vitality of thousands of ham clubs. If the League were interested in pushing PR they would encourage clubs to pro-

mote ham programs on broadcast radio and television all over the country and to acquaint our public officials with our hobby. There is a tremendous job to be done.

It is all up to you. I'll be watching the fine print in QST for this year's report on the board of directors meeting to see what our future looks like.

Irrelevant Note

One of the nice things about living up here in the backwoods of New Hampshire is that you can go to a country auction every Saturday night. The darndest things turn up there. The other night I lucked into a bunch of those old wooden jig saw puzzles. I dig those the most and snapped them for a dollar. Back in the early thirties we used to rent them from Womrath's and our whole family would struggle over a thousand piecer on holidays. Then came those confounded cardboard puzzles, stamped out instead of hand cut. Ugh.

Now and then I rent a puzzle from an outfit in New York. It's nice when the bends are loaded on weekends. Say, if any of you have some of those wooden puzzles you're thinking of throwing out, even if a piece is missing, let me have a chance at it.

I'm also keeping a weather eye peeled for a pottery kiln, in case anyone around the East has one extra. I can swap a complete press for making QSL cards with a half dozen trays of type. Or what do you want?

And we're looking for a pet type Burmese kitten. That's about all.

... Wayne

Liberian Field Day

If you need Liberia for WTW, your big opportunity is just around the corner. The Liberian Radio Amateur Association will hold its Third Annual Field Day Activities on April 29 and 30. The club station EL2FD will operate SSB on 14303 and 21303 kHz from 1400 to 0100 GMT on Saturday and from 0900 to 0100 GMT Sunday. A CW station will be on 14103 kHz. The RTTY boys will have a chance too—that is if the teletype equipment at EL2FD will work. Look for them on 14090 kHz.

The purpose of this annual field day is to demonstrate amateur radio and encourage the local people to become hams. QSL cards will be sent to every station contacted. The QSL cards are on hand and will be filled out on the day of contact.

WANTED

SALES ENGINEERS EARN

\$20,000 per year

Based on commission from sales and installation of just 3 Vanguard TV cameras per week!

Full or Part Time

Closed circuit TV is recognized as a definite necessity for many businesses to combat rising costs. Thousands of factories, office buildings, banks and schools will welcome your demonstration.

Using our list of applications as a guide you will be able to show how any establishment can use several cameras and how each one can save thousands of dollars through the resulting increase in efficiency and security.

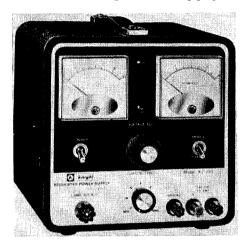

If you are over 21, have a working knowledge of TV and are financially responsible, we need you as a sales engineer to demonstrate our Model 501 in your area. To receive your application and additional details, send us a resume of yourself and include a self-addressed, stamped envelope.

VANGUARD LABS

196-23 Jamaica Ave. Hollis, N. Y. 11423

Knight-Kit Solid-State Regulated Low Voltage DC Supply

The new Knight-Kit solid-state power supply, with continuously variable 0-40 volts DC and 0-1.5 amperes output, provides an ideal source of power for transistor circuit development in the shack. This power supply, the model KG-663, is regulated for both line and load variations and features variable current limiting which automatically limits short-circuit current to a safe value. Two meters on the face of the supply simultaneously monitor voltage and current. A heavy-duty operation/standby switch allows presetting of output voltage with the load disconnected; pilot lights indicate standby and operate conditions. This supply also has fine and coarse voltage controls, a rear terminal strip for remote programming and sensing and isolated plus and minus voltage. These units are designed so that they may be stacked for series/parallel use.

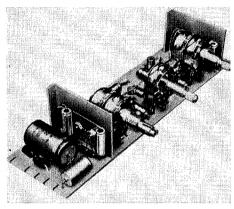

The KG-663 supply is very well filtered and regulated for low ripple output; less than 0.6 millivolts rms at full load. It is available in kit form for \$99.95, or completely factory assembled for \$149.00 from Allied Radio Corporation, 100 N. Western Avenue, Chicago, Illinois 60680.

Apollo Tie Clasps and Desk Plaques

Apollo Engraving, 191 N. Hickory Street, North Massapequa, New York 11758, is marketing a new line of tie clasps which are very neat and attractive and would make nice gifts and awards. Selling, delivered, for only \$1.50, the background is black, call letters white, and there is a commercial mike attached to the edge, giving it a very professional appearance.

Apollo also makes call letter desk plaques, on laminated plastic board 2½ x 6 inches, in black, mahogany, walnut or blond oak, with white call letters, and mounted on a clear plastic base with a metal edges, looks great on the operating table. This sells delivered for only \$2.50.

Amperex Printed Circuit Assemblies and Kits

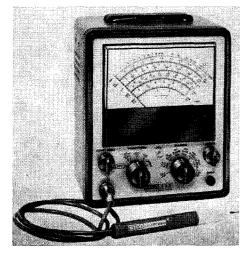

Amperex Electronic Corporation has just announced the introduction of a broad line of printed circuit assemblies and kits for the experimenter and hobbyist. The printed circuit assemblies are available for immediate distribution and the kits will be ready for June deliveries. These new units are designed for use in ham gear, home entertainment equipment, public address and intercom systems. Printed circuit assemblies presently available are 1 watt, 2 watt, and ³/₄ watt amplifiers using either 9 or 14 Vdc, several models of stereo amplifiers, a tape preamplifier and a 20 watt monaural amplifier. The amplifiers are available in various configurations that include tone controls, balance controls, no level set controls; an arrangement is available to suit nearly any requirement. For further information, write to Amperex Electronic Corporation, Semiconductor and Receiving Tube Division, Distributor Sales Department, Hicksville, Long Island, New York 11802.

Lafayette Spring Catalog

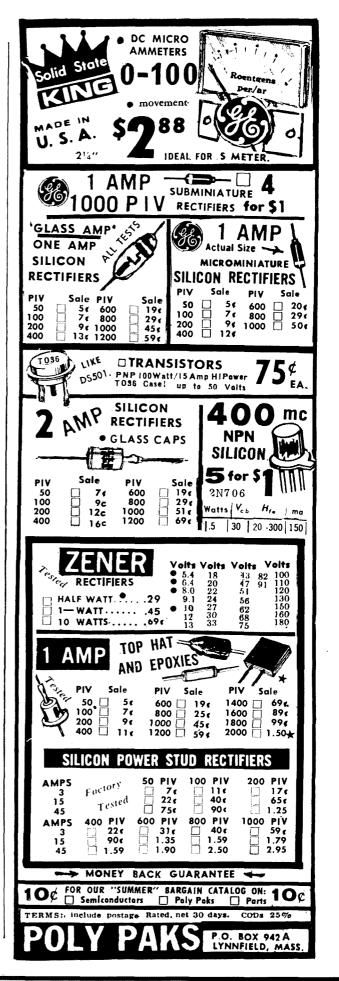

Layfayette has just announced its new Spring 1967 catalog with the latest in electronics and hi-fidelity. All of Lafayette's own top-rated components as well as equipment from many of the top manufacturers are represented plus a special six page clearance section with a host of values. There is a complete selection of ham gear, test equipment, tools, hi-fi components and electronics parts included. For your free copy write to Lafayette Radio Electronics Corporation, 111 Jericho Turnpike, Syosset, Long Island, New York 11791 and ask for catalog number 673.

A.R.C. Sales

A.R.C. Sales P.O. Box 12, Worthington, Ohio 43085 type of measurement is particularly useful when working with transistor circuits.

Operation of the instrument is made easier and more efficient by using a unique twocolor system of coding and coordination on the range and function switches and meter face. The dual purpose AC/DC Eico Uni-Probe also simplifies matters when making many measurements. Its 11 megohm input impedance makes for negligible loading in precision DC measurements from 0.01 volts to 1.5 kV in eight overlapping ranges. Both peak to peak and rms voltage are read on separate scales in seven overlapping ranges up to 1500 volts rms (4200 volts p-p). The basic frequency response of this instrument is 30 Hz to 3 MHz, but it may be extended to 250 MHz with an optional high frequency probe.

For further information on this versatile new VTVM, write to Eico Instrument Company, 131-01 39th Avenue, Flushing. New York 11352.

Tymeter Numeral Clock

If you don't have a numeral clock in your shack, the new Tymeter Colorama Tele-Vision Lamp Clock may be just what you're looking for. This clock has a good looking face and is available in several color combinations that will fit any decor; persimmon/white case, walnut case, or white case, priced respectively at \$14.95, \$13.95 and \$13.95. These clocks have a built-in light and come with a one year guarantee.

While time has been measured by mechanical clocks since 1363 when Henry De-Vick invented the earliest self-contained counterpart of the modern clock, reading dial faces results in loose time-telling. For amateur radio work, accurate time is a must, and with the numerical clock it's a snap. Write to Pennwood Numechron Company. Tymeter Electronics, 7249 Frankstown Avenue, Pittsburgh, Pennsylvania 15208 for more information.

Amperex Power Tetrodes

Do you want a single sideband linear that will really loaf along at the legal limit? The new Amperex 8679 and 8744 should fill the bill. Both of these tetrode power tubes were designed for use as low distortion linear amplifiers in class AB single sideband service and are rated at 4 kW and 10 kW respectively.

Under class AB conditions the 8679 will produce 5 kW PEP output with odd order distortion products down at least 35 dB. The 8744 will produce 10 kW PEP output with the same order distortion products in single sideband linear service. If you want the coolest linear in town, write to Amperex Electronic Corporation, Tube Division, Hicksville, Long Island, New York 11802 for full specifications and prices.

ATV Research Television Catalog

The new ATV Research Television Catalog is just chock full of goodies for the amateur television enthusiast. This catalog features a brand new transistor television kit, transistor camera parts for "do-it-yearself" experimenters including focus-deflection coil kits, tripods, lenses and all types of vidicon camera components. If you want to get on the ATV bandwagon, this catalog lists everything you need to get your station going. For a free copy, write to ATV Research. Post Office Box 396, South Sioux City, Nebraska 68776.

Silicon Controlled Rectifiers

Allan Lytel's new book on SCR's gives a complete explanation of these important new semiconductors. They are being used in new applications everyday because of their small size, versatility and reliability. This book thoroughly explains their principles of operation and illustrates how they may be used in numerous practical control circuits.

Phase-shift control of ac and dc power is clearly explained and examples of these circuits given. This book also discusses SCR ring counters, temperature controls, and voltage regulators. The chapter on SCR testing will be particularly useful to anyone working with SCR's. \$2.75 at your dealer or write to Howard W. Sams & Company, Inc., 4300 West 62nd Street, Indianapolis, Indiana 46206.

You won't be able to put it down!

We should give fair warning to those who order this new book from the Radio Society of Great Britain. Once you pick it up, you won't be able to eat, sleep, talk or watch TV until you've read it all. It's a fascinating, densely-packed, 100page book full of every imaginable practical circuit for ham radio. Hundreds of circuits and ideas are discussed, and each one is useful to hams. Here are the chapters: semiconductors, components and construction, receiver topics, oscillators, transmitter topics, audio and modulation, power supplies, aerials and electrical interference, troubleshooting and test equipment. Once you've digested this book thoroughly, you won't be able to build or modify any gear without consulting it. \$1.50

The View from Here . . .

With all the technological advancements that have been made in amateur radio in the past few years, there's no reason why we must perpetuate antiquity by using AM on any of the high-frequency bands.

I'm sure this will evoke a few cries from isolated corners, but the fact is, if you listen in on the bands below 30 MHz at any time of the day or night, AM stations in the American phone band are few and far between.

Ten years ago it was the other way around—sideband stations were in the minority. Even five years ago the gentlemen's agreement on twenty meters was useful—now it is ridiculous. The two or three AM stations operating between 14200 and 14250 do a lot of complaining about the sidebanders' violation of this archaic agreement, but they're the only AM stations on the band. Everyone else has gone to more efficient and compatible sideband.

When king spark was outlawed in favor of CW and modulated oscillators were eliminated from the high-frequency bands, there were cries of anguish from a few who had fallen behind the times. The same thing is true today. There are always a few who fail to keep the pace.

The spectrum that we have available is limited and there's not a chance in the world that it will be enlarged. There's even a good possibility that we'll lose part of it. At the very best we'll have to contend with more and more intruders. Therefore, it's incumbent upon us to use the space we do have available to the best advantage. Maximum utilizations of the bands available, cannot, within any stretch of the imagination, include the use of Ancient Modulation. Most amateurs are aware of this and have switched to sideband.

Not only do AM transmitters require much more bandwidth, they are inefficient and in many cases, ineffective. This has been proven many times in the past, both theoretically and practically. If you can copy a station Q5 on CW, about 90% of the time you can make a successful contact on sideband. Don't try it on AM-90% of the time you won't make it.

Although spectrum utilization and interference are the two big arguments against AM, there is one other important consideration—state-of-the-art. In years past, amateurs donated much to the advance of the radio art. As our technology sky-rockets forward, there doesn't seem to be an awful lot that the backyard experimenter and amateur can contribute. However, we can use the best techniques that are available—this doesn't include AM; it went out with 872 rectifiers, general coverage communications receivers and swinging links.

A lot of the AM procrastinators will holler about the high cost of sideband. Bunk! You can buy a high-frequency sideband transceiver today from five or six prominent manufacturers for about the same thing you paid for a good communications receiver a decade ago. If you don't like transceive operation, remote VFO's are available from most of the same manufacturers for less than a hundred dollars.

Kilowatt power amplifiers are no problem either—if it will work on AM, a few modifications will turn it into a linear. In most cases all that is required are a few changes in bias. While all tubes were not designed for linear operation, most of them will perform pretty well when properly biased.

Furthermore, the conversion of an AM transmitter to double sideband is a relatively easy operation. Although double sideband uses twice the bandwidth of single side-band, it has at least the same efficiency and the troublemaking carrier is eliminated. widespread use of single sideband has pretty much inhibited any serious experimentation with double sideband, but it appears to offer at least one advantage-synchronous detection. When a properly designed double sideband system with synchronous detection is used, QRM free QSO's are apparently the rule rather than the exception. Not that I'm advocating double sideband-I just think it deserves more investigation.

It doesn't really make a great deal of difference whether we use one sideband or two —either system is compatible with the other. Actually, there is little danger that double sideband will ever be very popular; single sideband equipment is too readily available.

None the less, AM is not compatible. It's not compatible with sideband, nor spectrum utilization, nor state-of-the-art. It's inefficient and ineffective. Isn't it about time we eliminated it from the high-frequency bands?

The Price of Progress

Dear 73:

... A few months ago I subscribed to 73 and had a rude awakening. I did not know the language well enough to read half the articles. Progress had run ahead of me and I was in bad shape. Since that time I have been trying to catch up and it's rough . . .

Just wanted you and your associates to know that you are greatly appreciated and I think you are doing a great job for the fraternity. Maybe some of the youngsters like to buy ready-to-operate, but there are still some of those left around that like to experiment and build our own. Again, thank you very much for the fine job you are doing. Keep up the good work.

Emery White, Sr. W4TQD Glasgow, Kentucky

Dear 73:

. . . Your magazine is getting better all the time and you may yet make a technician out of a mathematician. Hi.

John Bauer Kanata, Ontario, Canada

ORP

Dear 73:

The following might be of interest to younger hams and perhaps refresh the memories of some of the old timers. The following input powers were taken from QSL cards received from stations worked on 28 MHz in 1948. My call was then KZ5RS: OZ8J—12 watts; ZL1DW—70 watts; ZS1CG—25 watts; OQ5HL—60 watts; GM3BON—35 watts; and VK3PG—50 watts. My reports to these stations were 57 or better.

R. W. Stewart WA4EKF Warner Robins, Georgia

The sunspots do make a difference.

Transistor Circuits

Dear 73:

Congratulations on your article by W1DTY—too bad you cut off the "T" in his call on the front cover of the March 73. His 73 transistor circuits are going to be a big help to this ham and a lot of others I am sure.

S. R. Gross W90JI Wheaton, Illinois

Dear 73:

. . . the transistor circuits article in the March issue was a real dandy and received a lot of favourable comment from the boys around here.

George Cousins VE1TG Nova Scotia, Canada

Dear 73:

Only two tubes in the March issue—what did you do, fire the drawer of tube diagrams? If so, FB. Promote Fisk for his solid state jewel!

The Whole of The Doughnut

How to use toroidal tank coils in high power amplifiers for increased efficiency with reduced size. Practical inductors are shown for 100, 500 and 1000 watts.

Toroid rf tank coils have brought a new era of construction technique to the amateur builder as well as commercial manufacturers. Spurred on by modern requirements for compact construction, the toroid has seen recent applications in DC to DC power converters, interstage audio transformers, and many other uses. Indeed, the largest single application of the toroidal coil is the television flyback transformer which has been taken for granted for years in the home TV set. Recent articles have described toroidal coil applications in VFO's,1,2,3 low power transmitters,4 VSWR meters5 and multi-band tuners6. Now, for the first time, the outstanding advantages of toroids have been realized in higher power transmitter rf tank circuits.

The impact of toroids upon modern electronic equipment design has been of first order importance. Not since the advent of transistors or SSB itself, has so important an advance in construction technique been available to the electronics industry. Significant reductions in size, ease of packaging and improved efficiencies lead the list of reasons why toroids have emerged as the currently favorite tool of electronic designers.

Advantages of toroids

The most significant feature of the toroidal coil is that its magnetic flux is almost entirely contained within the coil itself. This means that generous spacing

of the coil from adjacent components, panels and chassis need not be provided. Further, by virtue of using a powdered iron core within the coil, an adequate inductance can be achieved with fewer turns, smaller diameters and resultant smaller physical sizes. When fewer turns are used for the coil, larger gauge wire can be accommodated. Also, if the flux is restricted within the coil, greater Q and improved power transfer efficiency are achieved. These factors add to accomplish less heating loss within the tank coil assembly itself, resulting in more power output.

In rf tank circuits for example, we are able to achieve a volumetric size reduction of better than 8 to 1. Part of this is due to the fewer turns and smaller diameter winding which is possible. More importantly, however, less spacing is required around the coil to accomodate its magnetic flux, because this flux for the most part is contained within the toroid. Therefore, a favorably high Q is achieved without spacing the coil at least one diameter away from the chassis as would normally be required with conventional construction. While promise many desirable features, several new design considerations must be recognized. The higher Q presented by a toroidal coil makes its tuning relatively sharp. This is particularly true when tuning an unloaded or lightly loaded tank circuit. There-

6 73 MAGAZINE

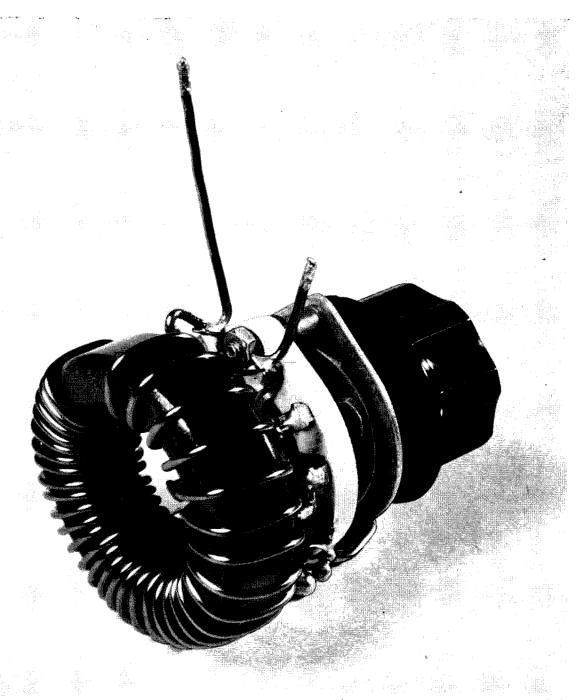

Fig. 1. Toroidal rf tank coil for use in a 100 watt transmitter. The powdered iron core provides High-Q and therefore, good energy transfer. Compact construction results in a tank coil only a fraction of the size normally encountered in conventional designs. The core is given several coats of epoxy cement prior to winding so as to prevent flash-over from the winding to the core. fore, when a toroid is used in a transmitter final tank circuit, it may be necessary to "re-dip" the final more often than a conventional circuit when changing from one operating frequency to another. Also, when the quasi-conductive powdered iron core is placed within a high power rf tank coil, some tendency toward flash-over to the core is experienced. However, with proper precautions

and adequate spacing as described later, this tendency can be eliminated.

The toroidal core

Cores for the toroidal tank coils described in this article were obtained from Ami-Tron Associates, 12033 Otsego Street, North Hollywood, California. Their model T-200-2 was selected for its large size (2 inch out-

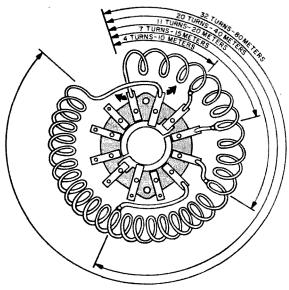

Fig. 2. Winding data is given here for the 100 watt coil. Enameled copper wire (#14 AWG) is used. Windings have a greater spacing at higher frequencies in a manner typical of multi-band tank coils.

side diameter) and 2 kW PEP rating from 500 kHz thru 30 MHz. This same core is used in the Ami-Tron Signal Antenna Balun Kit.

Powdered iron cores are manufactured from iron ore by a process called "sintering". While several special proprietary processes enter into their fabrication by different manufacturers, the essential process requires a thorough dehydration by baking and pulverizing of the iron ore. The resultant iron granules are then compacted or sintered in a properly shaped mold under extreme pressure and high temperature. Organic binders are generally not used. Rather, a mechanical inter-granular adhesion is achieved which produces a solid mass with each iron granule being electrically quasi-insulated from the rest. This is needed, as we know, to prevent hysterisis losses and is analogous to the

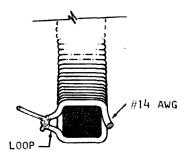

Fig. 3. Taps for connecting to the band change switch are made to small "U" shaped loops in the wire. These loops are placed on the edge of the coil facing the switch and leads are only about 1/2 inch long. The switch is a Mallory ceramic wafer switch.

insulated laminations in a conventional power transformer or choke coil. Higher frequency applications require smaller granule sizes.

The 100 Watt toroid

In our experimentation with toroids in rf tank circuits, three different sizes were selected to satisfy three different power ranges; 100 watts, 500 watts and 1000 watts. The builder might well use somewhat higher or lower powers in connection with the physical sizes of the coils illustrated here.

Corona flash-over to the iron core mass is eliminated by first coating the T-200-2 toroid core with several coats of epoxy cement. Teflon, vinyl or fiberglass tape may also be used for this purpose. Fig. 2 gives the winding data and shows the placement of taps which are connected to a ceramic wafer band change switch. Number 14 AWG enameled copper wire is used. The windings for the 10, 15 and 20 meter portions of the coil are spaced out at the center of the toroid equal to the wire diameter. The remaining 40 and 80 meter portions of the coil are close spaced at the toroid center.

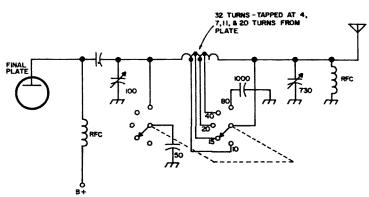

Fig. 4. Schematic of a typical pinetwork. Additional fixed capacitance is provided at both the input and output in the 80 meter position. This permits smaller tuning capacitors to be used.

Taps to the toroid tank coil are made by forming a small loop in the winding as shown in the cross-section, Fig. 3. Stout needle-nose pliers are used for this purpose. After all windings are completed, the enamel is scraped from the loop and short sections of the #14 buss wire are soldered on, completing the connections to the band change switch. These short sections provide a rigid mounting of the coil to the switch and permit the completed assembly to be panel mounted.

The reader will note that a double pole wafer switch was selected for the 100 watt toroid tank coil. This permits the switching in of a fixed 50 pF padder capacitor on the 80 meter band as shown in Fig. 4. Consequently, the smaller 100 pF variable tank capacitor can be used, resulting in further space and cost savings. In the 80 meter position, a switch tap is also available for padding the output or antenna loading capacitor.

Winding toroids

When winding toroids commercially, specialized machines are used. Large numbers of turns are made by passing a bobbin of wire thru the toroid on a circular guide ring. Winding rf tank coils with heavy gauge wire presents a whole new family of problems. The toroids in this article were all wound by hand with a pre-determined length of wire.

The builder's first inclination is to hold the core in a bench vise and pull the turns taut with pliers as shown in Fig. 5. Don't do it! A broken core is bound to result. The core should be held by hand and each turn is pressed into place. While this is a challenge to the strength and endurance of one's fingers, it is necessary for successful toroid construction. Powdered iron cores are fragile and if one happens to be dropped or otherwise broken, it can be cemented together again as shown in Fig. 6. Remember, that insulation between the iron granules of the core is fundamental to its design. Avoid use of organic cements which deteriorate with heat or age.

The following are a few pointers which will ease the task of designing and winding toroids employing heavy gauge wire:

1. If the proper number of turns is not known, wind the coil first with small size bare wire. It will be easier to wind, easier to space out the turns and more con-

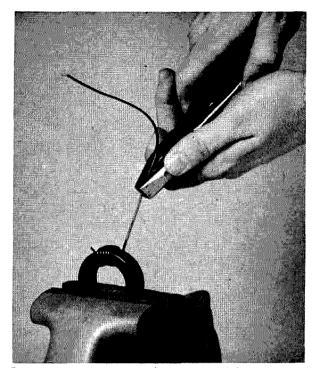

Fig. 5. How not to wind your toroidal coils! The fragile core is sure to break if heavy wire is pulled taut with pliers. When winding toroids, the core should be hand held, and the wire pressed into place with your thumb.

venient to solder on taps to verify where they should be placed. After making the necessary electrical measurements, the small wire can be clipped loose, discarded and replaced with wire of the proper size.

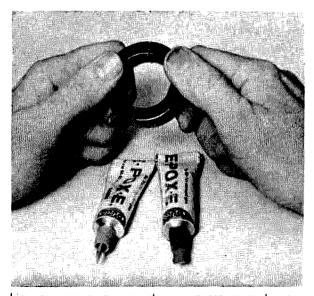

Fig. o. Droken powdered from cores may be repaired with epoxy or household cement. Core material is a quasi-insulator and electrical contact between the broken pieces is neither required nor desired.

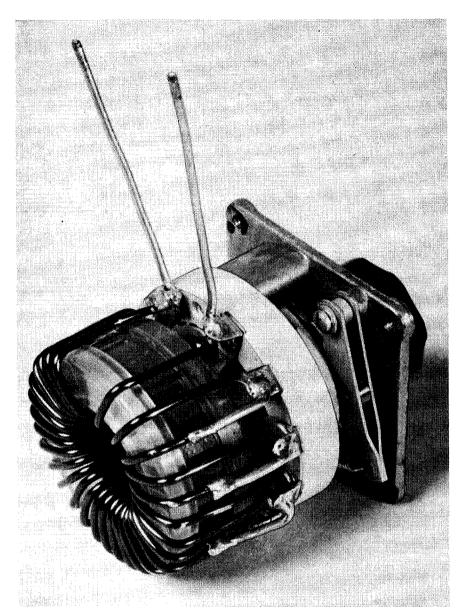

Fig. 7. Medium power (500 watt) toroidal tank coil employs one powdered iron core. The polystyrene endspacers prevent flashover from the winding to the core. Coil taps for the various amateur bands are made to the outside of the windings that bridge across the two end spacers.

- 2. The length of heavy gauge wire required should first be calculated or simulated with string. This will avoid the inconvenience of threading an excessive length of wire through the toroid and will eliminate wastage when cutting off the surplus after the proper number of turns are reached.
- 3. Note the direction to which the windings advance; left to right. Determine the proper winding direction so that taps for the various bands proceed from left to right when viewing the band switch from the front panel.
- 4. Prior to starting the winding, straighten the wire and remove kinks. This can be done by holding one end in a bench vise and jerking the far end with a pair of pliers. Alternately, the far end can be

- twisted an equal number of turns to the right and then to the left with a hand drill. Avoid excessive working of the copper which causes it to harden and become more difficult to handle.
- 5. Start winding from the center of the measured length of wire and work toward each end. This eliminates passing the total length of wire through the toroid core on each turn. It also minimizes work-hardening of the wire and kinking due to excessive handling.
- 6. Press wire firmly in place on each quarter-turn so that tight windings and neat right angles are obtained on each turn.
- 7. Prior to passing the free end of the

wire thru the core, unwind the last quarter turn slightly. This permits the wire to thread through parallel to the axis of the core and avoids kinks.

8. When spaced turns are called for, first wind them close spaced. After the proper number of turns are in place, space them out to the desired locations. This results in neater windings and tends to tighten them upon the core.

500 watt toroid coil

Fig. 7 shows the 500 watt toroid. An Ami-Tron T-200-2 core is also used with this coil. The band change switch pictured with the coil is the husky tap switch taken from a surplus BC-375 antenna tuning unit. These are still available for little cost from surplus dealers who advertise in this magazine. If a new switch is to be purchased for this purpose, the Ohmite power tap switch model 111 or 212 will work very well.

The reader will observe that insulating end spacers have been employed to hold the wire away from the powdered iron core material. About one-eighth inch of space is thus provided and has served well to prevent flash-over from the coil to the core. This spacing is about equal to that usually used between the rotor and stator of a tank capacitor selected for this power level.

Enameled copper wire of #12 AWG size is used for the 500 watt toroid coil. It is wound using the same general instructions as used with the 100 watt unit. Because a larger coil diameter results from use of the end spacers, fewer turns can be employed. This is a welcome advantage due to the smaller inner diameter of the end spacers and less space which is available for the windings. Fig. 8 gives the winding data and tap information for the amateur bands from 80 to 10 meters inclusive.

1000 watt coil

Fig. 9 illustrates the high power coil which is suitable for 2 kW PEP on single sideband. The 10 meter portion of the coil has been externally wound. This was done to provide further isolation of the high impedance or highest voltage end of the coil from the powdered iron core. Copper tubing of 3/16 inch diameter is used for the 10 meter coil and #10 AWG tinned copper buss wire is used for the remainder of the coil within the toroid core.

In the 1000 watt coil, two Ami-Tron T-200-2 toroid cores are used to minimize the possibility of core saturation and "flat-topping". Prior to winding, the two cores as well as the end spacers are cemented together with epoxy cement. This makes winding of the coil much easier. Alternately, the two cores and two end spacers could be temporarily clamped together or lashed with string until the initial windings are in place.

The heavy duty band change switch is again used as previously described. Even with the greater mass presented by the two cores and heavier wire, no problem was encountered in making the complete assembly rigidly panel mounted by short pieces of #10 AWG copper buss connecting the taps to the band change switch. Fig. 10 provides the winding data for the high powdered coil. This spacing is ensured by placing small ¼ inch by 2 inch pieces of 1/16 inch aluminum or plastic between the turns at the center of the coil. After proper and uniform spacing is achieved the individual turns are secured to the end spacers with epoxy cement. The temporary spacers can then be removed.

End spacers

Polystyrene sheet % inch thick is used to

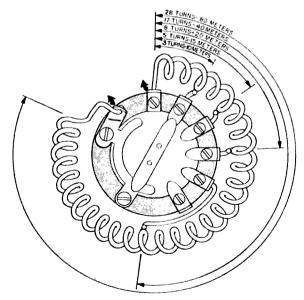

Fig. 8. The medium power toroid tank coil uses a surplus switch from a BC-375 Antenna Tuner. Windings are made with #12 AWG enameled wire. Fewer turns are required when the end spacers are used due to their producing a larger effective coil diameter. The 10 and 15 meter windings are spread out slightly more than the rest of the coil.

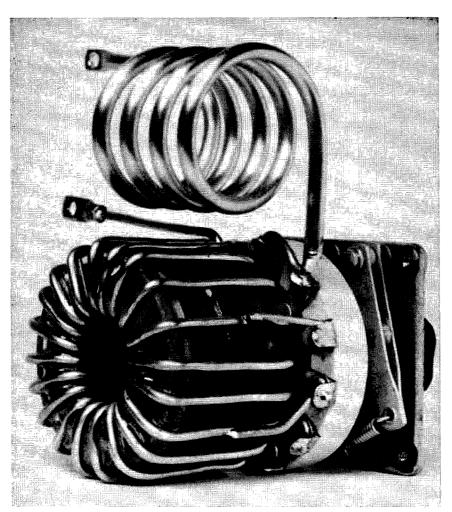

Fig. 9. High power tank coil for 1 kW operation. Two cores are stacked to lessen the possibility of core saturation. Larger wire (#10 AWG) is used in this model. The same heavy duty band change switch is used for this and the medium power version.

make the end spacers. Fig. 11 gives the dimensions of these pieces. Lucite or bakelite should not be used due to their inferior dielectric strength. The end spacers can be readily make on a lathe or can be cut out and recessed by means of a chassis fly-cutter in a drill press. If the end spacers are to be cemented to the toroid core, it is not necessary to cut the circular recess in them as pictured.

Tap connections

Fig. 12 shows alternate methods of securing tap connections to the toroid coils. Good success was achieved by providing about a ½ inch overlap of the tap lead on the coil winding. Solder is cautiously flowed on both sides of the tap taking care not to melt the polystyrene end spacer material. When assembling the coil to the band change switch, it is desirable to first form and solder the two major coil ends to their proper terminals on the switch. This serves to position the coil and makes it more convenient to form the taps and solder them in place.

Coil measurements

A Boonton Q Meter is invaluable in the empherical design of coils. However, such an instrument is not generally available to the amateur constructor. In lieu thereof, a grid-dip meter and calibrated capacitor will serve for frequency determination. A recent article in 73 Magazine⁷ described this method. The three toroid tank coils were measured on a Boonton Q-meter and the following unloaded Q values were recorded:

Band	100 watt	500 watt	1000 watt
80	310	360	332
40	177	200	190
20	160	205	188
15	132	186	190
10	128	146	250

The lower Q values measured at the higher frequency bands are due to the coil being "bunched-up". That is, the small number of turns occupy only a fraction of the total core length. To achieve maximum Q for any given number of turns, those turns should be spaced out evenly over the whole core

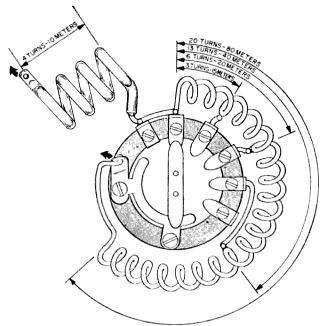

Fig. 10. The high power coil utilizes two powdered iron cores whose larger winding cross section requires that still fewer turns be used than for the medium power coil. While it is optional with the builder, in this case, the 10 meter section of the tank was externally air-wound. This is desirable because it reduces the electro-potential stress between the "hot" end of the coil and the core. Four turns of 3/16ths inch diameter copper tubing are wound on a 1/4 inch diameter form and spaced out to 13/4 inches long.

length (or circumference). This situation is always encountered with a multi-tapped coil. It is interesting to note that the high power 10 meter coil has a relatively high Q. This is obviously due to its heavy construction, optimum length/diameter ratio and the fact that it is self-supporting, external to the toroid.

Fig. 13 provides a handy guide in determining the value of tank capacitance to be used in resonating these coils. Of course, the first step to be taken when designing a resonant tank circuit for your transmitter is to select the proper L/C ratio to match the tubes output impedance. The toroid coils described in this article are suitable for most tubes in common use today. However, if several amplifier final tubes are paralleled as is frequently done, the reader should be guided by the references on this subject in one of the amateur radio handbooks to obtain a proper L/C ratio.

The future of toroids

Having already gained wide spread use in

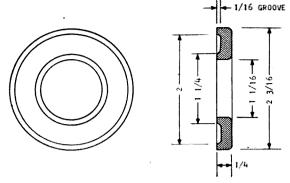

Fig. 11. Drawing showing dimensions of end-spacers used on both the medium and high power toroidal tank coils. Polystyrene, 1/4 inch thick is used to make the end-spacers by means of a chassis fly-cutter mounted in a drill press. Wire tension and friction hold the end-spacers in place.

many lower power applications, toroids can now be used to great advantage in high power transmitters. Perhaps before long, commercial transmitters will be using toroids. In the meantime, the amateur may avail himself of their superior compactness and efficiency and thereby continue the pioneering heritage which has earned the amateur radio operator and constructor his place of respect today.

Acknowledgement

Mr. Joe Williams, W6SFM, of Ami-Tron Associates was most helpful in furnishing toroid core material, technical advice and encouragement in developing the coils described here. To Mr. Paul Sellers, W4EKO, goes thanks for early design criteria and the pioneering approach to high power toroid rf coils. The assistance of Mr. Frank Emens. W4HFU, was invaluable in making coil measurements, and Mr. Jim Bauman and

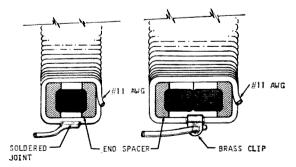

Fig. 12. Details of alternate methods for making the tap connections to the toroidal tank coils. Care must be taken to prevent solder from bridging over to the core, thus promoting a flash-over. Excessive heat must be avoided when soldering near the end-spacers so as to prevent their being melted.

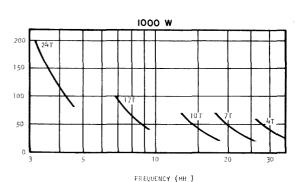

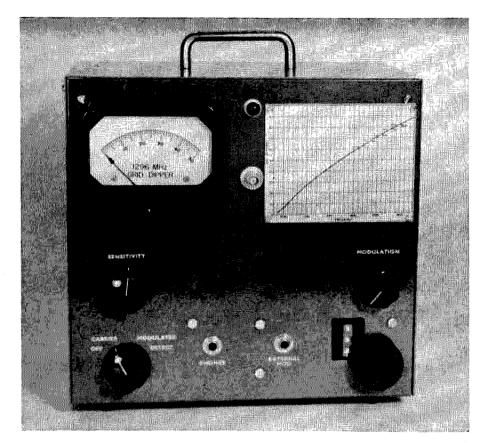

Fig. 13. Charts showing the capacitance required to resonate the three toroid tank coils on the five amateur bands. The L/C ratios obtained on each band match the tube impedances most frequently used today. If a very low tube output impedance is encountered, such as found in paralleling of many TV tubes, a much lower L/C ratio would be called for.

A 1296 Grid Dipper

Conversion of the APX-6 transponder to a grid-dip oscillator that covers from 1050 to 1320 MHz.

One of the big problems with operating on 1296 MHz is locating the operating frequency of your equipment. Not only is the newcomer faced with this problem—any longtime resident on 1296 will attest to the many checks he has made to ascertain operating frequency and band edges. Some UHF amateurs have been able to obtain signal generators that cover the 1215 to 1300 MHz band, but many must resort to the time-proven lecher-wire system for any meaningful frequency measurements on this band.

Each of the systems commonly in use suf-

fer from one disadvantage or another. Moreover, there is no commercial grid dip meter on the market, to my knowledge, which will cover this range. Most of them stop at 1000 MHz or so. This conversion of the APX-6 is not difficult and results in a very versatile grid-dip meter. Like its lower frequency counterparts, it may be used for dipping resonant circuits, detecting rf energy or as a signal source. The built-in Veeder-Root counter provides excellent frequency readout and the internal gear system ensures repeatability.

The only part of the APX-6 you need for

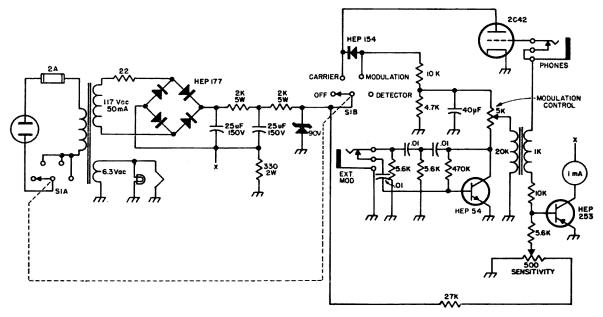

Fig. 1. Schematic diagram of the APX-6 grid-dip oscillator. Note that a 2C42 is used in the oscillator instead of the original 2C46. The built-in bypass capacitors and cavity inductance are not shown in this drawing.

this conversion is the cavity assembly. You can buy the door assembly of the APX-6 from many surplus dealers, but this contains the if strip which you don't need. In any case, the cavity assembly, with or without the if strip can usually be obtained for less than ten dollars. I picked mine up at an auction for five bucks-the original owner had started to convert it but evidently had given up. No matter, the transmitter and T-R cavity don't serve any useful purpose in this conversion. In fact, if you can obtain an APX-6 that has already been converted for use on 1215 MHz, by all means do so. Many times units that have already been converted go for much less. The only requirement for this that the conversion is receiver local oscillator cavity has not been disturbed. This is the case in most of the popular conversions.

The first step in this conversion is to pull out the tubes and separate the cavity assembly from the door. Now remove the screws holding the cathode cavity plate to the cavity body and the six screws holding the cavity body to the gear and counter housing. To remove the cavity body, pull it straight up from the casting. With the unit broken down to its three main parts, we can start the

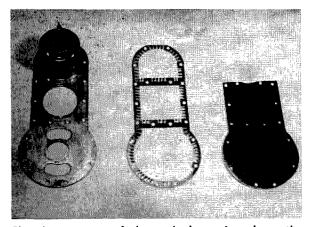

actual conversion process.

First of all, pull the plate off the back of the gear housing. Inside you will find three sets of bevel gears and the rest of the paraphenalia that translate cavity plunger move-

ment into numbers on the counters. Turn one of the counters up to 999 or down to 000. Note the tab on the horizontal gear which engages with the tab on the small bevel gear to prevent further movement of the tuning plunger. As you look at the casting from the rear, the receiver cavity is on the left, the diplexer (transmit-receive) cavity is in the center and the transmitting cavity is on the right.

Remove the five screws which hold the bottom plate on the housing and carefully remove it from the casting. It has to be pulled straight out. Three long pins with small locating tabs at the top are mounted on this plate. These tabs fit into keyways located in the tuning plungers. The receiver and diplexer plungers are removed by pulling them out from the gear end; the transmitter plunger is lifted from the top after unscrewing it from its drive gear. Now remove and discard the transmitter and diplexer Veeder-Root counters and gear trains. To remove the ¼ inch drive shafts (on which the knobs were mounted), drive out the small retaining pins with a pin punch.

Unscrew the receiver tuning plunger from the gear assembly and cut % inch off the end. This can be done on a lathe by any machinist or, with care and a very fine hacksaw, at home. To prevent undesired resonances the cut must be exactly perpendicular to the plunger axis-this is best accom-

The three pieces of the cathode cavity plate—the modified plate to the left, the serrated contact ring in the center and the new plate cover on the right.

plished on a lathe. Handle the plunger very carefully so the surface is not scratched. If it is damaged, the diplexer plunger may be used as a substitute.

While the plungers and gears are out of the housing, remove the shoulders around the transmitter and diplexer drive shafts on the front of the casting. If these shoulders are not cut off with a hack saw or filed down, the completed unit won't sit flush against the new front panel.

After the piece is cut off the tuning plunger, screw it on the gear drive assembly and push it through the contact fingers on top of the gear housing. Set the Veeder-Root counter to 000 and put the bottom cover in place. Now you have to do a little juggling. Adjust the plunger so it just protrudes through the contact fingers. Now mesh the drive gears so that the *stop* tabs engage. Usually you'll have to move the gears a few teeth each way to get the shaft to stop with the counter on 000. When the gears are all lined up, install the screws in the bottom cover.

The first step in the conversion of the cavity body is to remove the large coaxial connector. Remove the screw from the split collar which holds the connector on the front of the cavity. When the screw is removed you should be able to rotate the connector in the collar. The center contact is soldered to a pickup loop which is located in the wall between the diplexer and transmitter cavities. When this joint is unsoldered the connector may be easily removed. Remove the collar by unsoldering it from the front of the cavity.

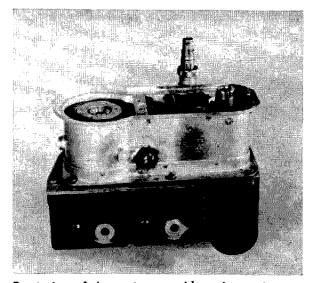

Cut out a piece of copper 1-23/32 inches wide by 2-1/4 inches long. This will be used

as a partition in the center of the old diplexer cavity. If you cut this partition a little larger than required and form lips at the edges, it may be force-fit into the diplexer cavity and no soldering is required.

Look down inside the receiver cavity. You will note that the plate voltage is applied through a feedtthrough capacitor (C403) to a piece of wire which winds spirally around the plate line. Unsolder this wire from the capacitor, remove the three retaining screws and pull out the plate line. This line must be shortened by ½ of an inch. This is most easily accomplished with a tubing cutter.

In the unmodified APX-6 the local oscillator energy from the receiver cavity is coupled into the crystal mixer with the small loop adjacent to the aperture in the cavity wall. Somewhat heavier coupling must be provided for grid dip service. Cut a strip of copper ¼ inch wide and about 2½ inches long. Form a short tab on one end of this strip and solder it to the bottom of the receiver cavity about ¼ inch out from the wall. Put a "Z" bend in it as shown in Fig. 2. and solder it to the contact on the crystal mixer. After the new coupling loop is in place, put the modified plate line back in place and reconnect the B plus line to the feedthrough capacitor.

Unscrew the connector from the crystal mixer and pull out the diode. Remove the crystal retaining fingers from the BNC connector with a pair of pliers and push an awl through the ceramic capacitor which is built into the connector. Remove the pieces of ceramic and pull out the center contact.

Front view of the cavity assembly and gear housing before installation of the cathode cavity plate.

Save this female pin. If the ceramic capacitor is not removed, all of the 1200 MHz oscillator

energy will be bypassed to ground.

If you look closely at the back end of the mixer assembly you will see a round cover plate which is soldered in place. You will also see that a small hole has been drilled through this plate. Form a small hook in the end of a piece of #16 buss wire and hook it through this hole. Heat the cover plate with a small torch and when the solder is softened, pull the plate free with the buss wire. Solder a two inch length of #18 wire to the center contact of the mixer assembly and run it up through the connector body-cut it so it extends 13/16" above the threaded shoulder. Solder the female connector pin to the end of this wire and replace the BNC connector. Replace the round cover plate on the rear of the old mixer assembly and solder it in place. Modifications to the cavity body are now complete.

Unsolder the diplexer cavity from the cathode cavity plate and discard it. Discard the transmitter cathode cavity and saw off the grid contact fingers which extend above the plate at the transmitter end. Using the cathode cavity plate as a guide, cut out a piece of thin aluminum as shown in the photographs to cover up the holes. This cover serves no functional purpose, but it does make a neater looking unit. All that is left are the modifications to the receiver cathode cav-

If you look inside the receiver cathode cavity, you will see that the grid contact is suspended from the top of the cathode cavity with three wires. These wires are soldered to both the cathode cavity and the grid ring. Carefully unsolder the support wires from the top of the cavity and pull out the grid ring; remove the three wires. Enlarge the three holes in the top of the cavity with a reamer, install three 500 pF feedthrough capacitors (Erie X5UO 501M or equivalent), and solder them in place. These feedthroughs consist of a coaxial shell and are actually only half a capacitor-when you run a wire through the center, the capacitor is formed. If you can't locate this type of capacitor, you can make your own by unsoldering and removing the center conductor from a conventional feedthrough capacitor.

Solder three 1½" lengths of #16 buss wire to the grid ring and put it back in the cathode cavity with the new support wires going through the feedthrough capacitors.

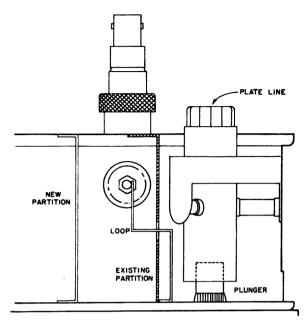

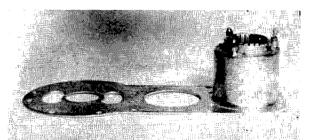

Fig. 2. Cutaway view of the APX-6 receiver cavity showing the location of the new pickup loop.

Place the 2C46 in the cathode cavity and use it as a guage for placing the grid ring in the proper position. When you have everything all lined up, solder the three supporting wires to the feedthrough capacitors. It's a good idea to check for shorts between the grid ring and the cathode cavity before soldering everything down—they should be electrically isolated for dc.

The APX-6 cavity modifications are now complete. It will tune smoothly from about 1050 MHz to well over 1300 MHz and grid current may be monitored in the modified cavity. All that is left is the power supply and modulator.

For maximum stability the power supply is regulated with a zener diode. The ninety volt supply is more than adequate for this purpose—when the grid is shorted to ground the grid current is nearly 1 mA. With the 10,000 ohm grid resistor, grid current is on the order of 150 A. A 200 microampere meter

Closeup view of the modified APX-6 local oscillator cavity showing the installation of the grid-ring feed-through capacitors.

ity.

is ideal for this grid dipper, but since I had a large 1.5 mA meter which I wanted to use, I incorporated a simple transistor meter amplifier. The negative supply voltage for the amplifier is developed across the 330 ohm resistor in the power supply. The meter amplifier transistor and bias resistors are mounted on a small piece of Vector board which is mounted on the meter terminals. If you don't want to use the meter amplifier, simply connect the meter between the arm of the sensitivity control and ground.

Modulation of the oscillator is provided by the 1000 Hz transistor phase-shift oscillator—modulation is adjustable up to about 90%. The oscillator is constructed on a small piece of Vector board which is mounted behind the APX-6 cavity on the main chassis. A jack on the front panel may be used for external modulation—a three to four volt audio signal will provide 90% modulation.

I built the chassis for my APX-6 grid-dipper from sheet aluminum, but a standard 12" x 11" x 8" utility cabinet can be used if you don't like to bend aluminum. My chassis is 11" wide, 10½" high and 5½" deep and consists of two U-shaped pieces. Bracing is provided by two brackets across the top and bottom as shown in the photographs. These brackets are made up from do-it-yourself aluminum angle and actually

serve two purposes. In addition to strengthening the chassis, three tapped holes in each bracket accept the cover retaining screws. The front panel is laid out as shown in Fig. 3. Even if you don't use this type of chassis construction, it is recommended that you use this panel layout.

The parts placement was chosen to provide a balanced layout. This means that all the available space is used. In fact, the two phone jacks occupy space previously taken up by the discarded counters in the gear housing. If they are moved to any great extent, they will interfere with the gear housing. The layout for the square counter cutout and five cavity mounting holes are not shown in Fig. 3—these are best obtained by using the old APX-6 door as a template.

Construction is quite straightforward and no problems should be encountered. Note, however, that the phone jack in the grid lead must be isolated from ground—this is easily done with fiber washers. Since the jacks are hidden by the gear housing when the cavity is attached to the front panel, wiring to them is run through the small screw holes drilled in the bottom of the housing. These holes were originally used to hold the counters in place.

The output of the oscillator is connected to the front panel connector with a short

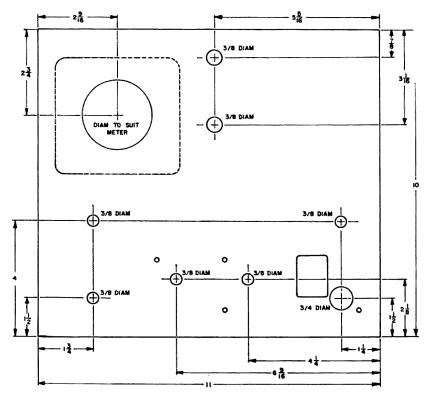

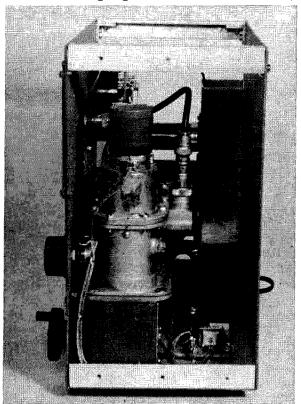

Fig. 3. Front panel layout for the APX-6 grid dipper. The locations of the square counter cutout and cavity mounting holes are not shown—they are best determined by using the old APX-6 door as a template.

length of coaxial cable. One of the newer Teflon insulated cables would be ideal for this purpose, but RG-58/U is perfectly adequate—that's what I used. Mismatch losses at the BNC connectors may be minimized by using the connector assembly diagrams in 73°.

Although a 2C46 was used in this cavity in the original APX-6, I found that it would not *always* oscillate in the modified cavity when power was applied. Substitution of the 2C42 from the old transmitter cavity solved this problem. An added bonus was the extra power output available with the 2C42.

Since there is a considerable difference in grid current between the oscillator and detector modes, be sure to turn down the sensitivity control before switching from one mode to another. If you don't, the needle will slam against the pin. It's also a good idea to turn the modulation control down when modulation isn't required. Since the meter indicates the relative magnitude of the modulating signal, less meter sensitivity

Inside the APX-6 grid dipper. The phase-shift modulator is in the right foreground, the power supply chassis is mounted on the rear panel. The cover is held with screws through the tapped holes in each of the four corner braces.

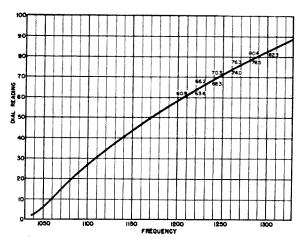

Fig. 4. Calibration curve of the APX-6 grid dipper. Counter readings for each 10 MHz point in the 1215 MHz band are included for accurate interpolation.

is required when the oscillator is modulated. If the modulation is turned up when you switch from carrier to detector through the modulated position, a bent meter pin is inevitable.

After you have completed the unit, all that is left is calibration. There are several approaches at this point, depending upon the type of equipment you have or can borrow. Lecher wires are the most straight forward but not necessarily the easiest. I used a General Radio 1140A wavemeter and an old surplus echo box and then made a double check with an LAE signal generator which covers this range. The calibration curve (Fig. 4) was then mounted on the front of the grid dipper for easy reference.

The completed unit tunes very smoothly through its range with no jumps in frequency. A few false dips in grid current appear around 1100 MHz, but in the main range of interest, 1200 to 1300 MHz, there are no false dips. In the detector mode, rf signals down to several millivolts provide an upswing on the meter. When used as an oscillating detector with headphones, significantly lower magnitude energy may be readily detected.

For the amateur who is interested in operating on the 1296 band, this grid dipper is a very useful piece of equipment. It may be used for tuning up converters, dipping out filters, detecting parasitics, determining transmitter frequencies and in tuning up frequency multipliers. In a pinch it may even be used as a low power transmitter by plugging in an external modulator.

Using FET's in the Command Set Transmitter

How to build a very stable VFO using a Command Set and three transistors—one FET and two conventional types.

Do you need a good stable VFO that's quite easy and inexpensive to build? Well I did, and after discarding many possibilities I came back to the old reliable Command

Bottom view of the transistorized Command Set. The oscillator section of the original Command Set is located on the rear of the chassis. In this conversion the chassis was cut in half and the rear part attached to the front panel.

Set. Tubes were definitely out—after all, who needs them with so many types of semi-conductors to choose from. Besides, the FET is supposed to behave like a tube, why not use it.

Hastily I attached an FET to the cathode, grid and plate pin of the oscillator tube. Boy, was I surprised—the oscillator took right off when voltage was applied without any component changes.

Enthusiastically, I began to remove everything from the chassis and decided to cut down its size as detailed in the Command Set* book. All parts except those associated with the oscillator were removed. The set was then rewired as shown in Fig. 1. The first transistor after the FET oscillator is operated as a class A buffer amplifier to isolate the oscillator from the output transistor and to build up the small signal to drive the next stage. The output stage is a broadband class C amplifier and only draws current when the oscillator is operating. No tuned circuits are used except the original circuit so the output is constant across

*"Command Sets," Copyright 1957 by Cowan Publishing Co., Port Washington, L. I., N. Y.

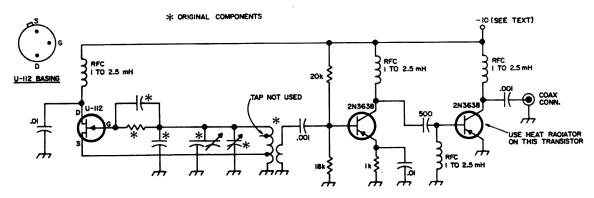

Fig. 1. Schematic of the transistorized Command Set transmitter. All components marked with an asterisk are original Command Set parts. The use of an FET in the oscillator circuit permits a simple and direct conversion from vacuum tube circuitry to semiconductors.

MORE COIL CHANGING

with the new improved

SWANTENNA

The only remote controlled band switching mobile antenna on the market.

5 BANDS-500 WATT

POWER RATING

We are pleased to offer the new band switching deluxe Swantenna as part of the Swan line. Two of the major improvements are the use of GE Lexan® in the center coil support that makes it virtually unbreakable, and the new light weight stainless steel whip. The higher Q of the Swantenna and the gold plated switching contacts provide greater radiation efficiency and field strength than most coil changing designs. Thus with the new improved Swantenna you achieve the ultimate in mobile operation; a high efficiency antenna system plus band switching while driving.

MODEL 55 remote controlled\$95

MODEL 45, same antenna as Model 55, but with manually operated coil switch \$65

Antenna Connector

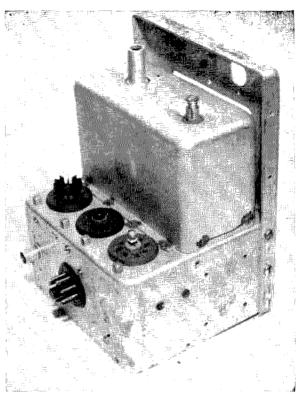

Disconnect your antenna from bumper mount in seconds. Made entirely of stainless steel. Noise free.

DELUXE BUMPER MOUNT

The most important development in mobile antenna mounts in years. No chain to break, no clip to stretch. Made of highly polished cast aluminum. Complete instructions illustrate how to fit this deluxe mount to the exact contour of your bumper,

providing the strongest, best looking mount for your mobile antenna.

ELECTRONICS CORP.
Oceanside; California

The shortie, transistorized Command Set. The transistor sockets are mounted in the center of the old octal tube sockets.

the band. With a 10 volt supply you get a full watt of input power to the final transistor. This is plenty enough to drive any crystal controlled transmitter.

All the HF Command sets were tried and the oscillator functioned perfectly. I won't attempt to give any of the basic data on converting the Command Sets. This information is quite readily available and would only bore most readers.

To keep the heat dissipation of the final transistor within safe limits, 10 volts is used for the supply voltage. Even with 10 volts a cap type heat radiator should be used. An increase of 2 volts more than doubles the power so be careful. When driving a Gonset Communicater III, for which this unit was designed, I find that dropping the supply voltage to 6 volts is more than ample to drive the transmitter to full output.

The transistors really carry a nice price tag, and should appeal to almost everybody. They are made by Fairchild Semiconductors and sell for about 62c apiece. The FET is a Siliconix unit. If another type is used it should have a transconductance of 1000 or better. If you really like pleasant surprises try this conversion.

. . . K3LCU

The Dichotomy of a Tube Man

Including the use of a FET in the BC-906 frequency meter.

It is hard to resist a winning combination, particularly when that combination happens to be articles and ads in 73 magazine. The spell-binders referred to are, "Field Effect Transistor Primer" by Jim Fisk¹ and "Two Transistor Testers" by Frank Jones.² Couple these with advertisements such as Poly-Paks and Meshna in which you find almost unbelievable semi-conductor and transistor bargains and you are lost.

When such a powerful coalition causes an old died-in-the-wool tube man to become a transistor enthusiast, that is an accomplishment. Would you believe a fellow who buys two assortments of 50 new, unused, 20-24 year old tubes for \$2.95 per assortment*, just to have them on hand in case? Hold on now, consider what electronic miracles you might perform with an orbital beam, hexode uhf amplifier, type 1630, Army Signal Corps Tube VT-128! Just to hold it in your hand and look at it is inspiring. It looks like a grown-up 955 acorn tube, except that it has 12 radial electrode wires instead of five. Into this world of dreams came WHAM, POW, SOT-Fisk and Jones et al.

After the order of solid state goodies arrive, you find yourself impressed by how few identifying marks are on the TO-5 and other style cases. In fact, you reminisce and recall that at least you could peek inside * 1964 Catalog, McGee Radio Company, Kansas City, Missouri.

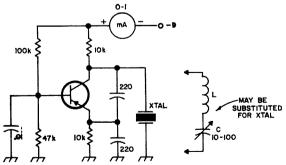

Fig. 1. Circuit for testing the oscillating characteristics of unmarked transistors. This circuit is shown with a negative supply for PNP transistors—for NPN units reverse the meter and use a positive supply.

the orbital beam hexode glass envelope and try to guess which is the grid, filament and cathode lead. At this point enter Frank Iones. Build up and use one of his transistor testers and the door of knowledge is opened. No longer do you care if you can't see inside. Everything becomes orderly. PNP's go into one box and NPN's into the other. The duds are set aside for Psuedo-Zener use. The sorting process turns into an exhilarating game. Plug them in, test, pull 'em out. You don't mind that after squeezing the three little wires between thumb and forefinger for the hundredth time, you have an excruciating cramp in the thumb! But wait; now that these wonderous things are sorted, how do you know which of them is "Power", "RF", "IF", "Audio", "Switching" and no test? Frantic thumbing through all issues of 73 from January 1962 forward was of little help for a solution to this new dilemma. In fact it was a hinderance. You find far too many tube articles which you remember wanting to try! Anyway, after having invested so heavily-at least \$10 so you can take advantage of the double bonus-it is incumbent upon you to take the next step to find out which of these little three-pronged rascals will oscillate. A circuit to help sort the unmarked transistors further is shown in Fig. 1.3

This is a Clapp transistor oscillator, either crystal or series L-C resonated. As shown, the battery and meter are set up for PNP's. Change the polarity to check NPN's, By using several crystals, for example, 450kHz, 2MHz, 3.5MHz and 7MHz or higher, you can learn which of the 100 or more bargain transistors in your possession will oscillate. It sure takes a lot of plugging but it's worth it. Imagine the thrill that shivers through your frame as you hear that crystal clear note in the station receiver. It takes you back to the days when-for old-timersafter you sawed two hacksaw slots at right angles across the bakelite base of a type 76 triode, between the four prongs, so as to decrease the dielectric shunting, you got the

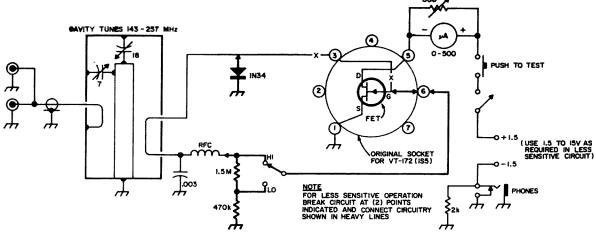

Fig. 2. Conversion of the BC-906 frequency meter to a field effect transistor. This frequency meter will detect rf signals down to a 100 microvolts or so and will tune through both the 2 and $1\frac{1}{4}$ meter bands.

tube to work at 2½ meters! For the younger man the occasion might be similar to uncorking his first 807 on 10 meters. At any rate, the yield of good oscillators from the packet of 100 bargain items is surprising. Many were vigorous to 7.3MHz. How well they will work in other circuits remains to be learned. It may be safe to assume that some of them will perform as rf amplifiers; how noisy they are can be learned from trial and error unless one uses the more modern transistor testers which are available at much greater cost than the simple ones referred to in this work.

The field effect transistors are indeed fascinating. It boggles the mind to think what would have happened to the radio-radarsonar systems had the solid state version of the tube arrived first. We'd probably be discovering the vacuum tube about now and that would be a blessing to those of us who need bi-focal glasses in order to work with these miniature components. Jim's FET Primer caused me to try the FET's offered by Poly-Paks. Again, the ones received are unmarked except that one is painted an ominous black. The advertisement seems to say that mine are low noise FET's made by Crystalonics. The package has a nice re-print from 73 and also some data which leads me to believe that one of the FET's is a C-610. Since my surplus BC-906E Frequency Meter had a 1S5 tube which went west, it was a logical choice to go FET. The original and modified circuits are shown in Fig. 2.

The FET can be plugged into the tube socket for experimentation, then later soldered in if you so desire. The schematics show the tube socket pin numbers in which to plug the FET leads. It is necessary to

remember that when looking at the bottom of the FET, the base lead is where the collector lead normally is located on a standard transistor. (Not on all FET's. Consult manufacturer's data sheet if in doubt. Ed.)

The absorption wave-meter with the FET performs much the same as the original tube version. One less battery is required and the battery voltage will depend upon the FET used. The FET which I assumed to be a C-610 works well with 1.5 volts. When the meter reads 500 micro-amperes full scale, the measured drain current is 1.5 milliamperes. As the cavity is tuned through a two meter rf field, the drain current will dip just as it did with the vacuum tube in the circuit.

The sensitivity may be improved by leaving out the 1N34 diode and disconnecting the 1.5 megohm resistor from the end of the radio frequency choke nearest the Hi-Lo switch. These modifications are indicated in Fig. 2 by the heavy lines. Then, with the rf lead from the cavity connected to the gate of the FET, the field effect transistor will act like an old-fashioned vacuum tube with a floating, leaky grid.

With this modification the frequency meter will respond to 100 microvolt signals fed into the cavity by way of the plug-in antenna. The fact that the FET will perform in this manner is a measure of compensation and a bit of solace to a hard vacuum tube man.

Del Crowell K6RIL 1674 Morgan Street Mountain View, California

Converting the Swan 120 to 6 Meters

With the continued upswing in sunspot activity, intercontinental DX on 6 meters is just around the corner. This simple and inexpensive conversion will provide a complete SSB transceiver for six.

This conversion makes a complete 180 watt PEP six meter transceiver with more features than the original 20 meter unit and compares favorably with commercial 6 meter units at much less cost.

General description

With the Swan single band transceivers consistently appearing on the used market,

Part of K6RIL's shack. The six meter Swan 120 is in the right foreground. The rack on the left contains a kilowatt and transverter for 432 MHz, a 2 kW PEP rig for six and a 2 kW amplifier and transverter for 144.

the SW 120 models may be purchased for a very reasonable price. This inspired me to investigate the possibility of converting one into a 6 meter transciever. The investigation seemed to prove that this was entirely possible.

I noticed that the Swan people left a lot of chassis room in the right hand side around the final section, so I decided to take a chance. A SW 120 was purchased for \$85.00 and the modification was started. I was quite amazed at how simple the modification appeared. As described previously, there is a lot of empty space under the chassis for adding extra parts.

New transmitter circuit

The transmitter conversion consists mainly of changing the original driver stage to a second conversion mixer and removing the original driver plate coil and all of the final circuits. The new driver, a 6CL6, operating in class A, and new final with 6146's operating in AB1 were added. In addition, a local oscillator with buffer was installed. These added parts fit into the empty space very nicely. When checking out the transmitter, two major problems were encountered. First,

Fig. 1. New circuit of the SW 120 for six meters. L4 and L5 are 8 turns number 26 on a 3/8" form. Relocate L5 and wire as shown. L6 and L7 are 5 turns number 20 closewound on a 3/8" form—use a white slug. L8 consists of 31/2 turns of 1/4" copper tubing—11/4" inside diameter, 23/8" long. Parasitic chokes PCI and PC2 are 2 turns number 22 wound around a 470 ohm. 1/2 watt resistor. PC3 and PC4 consist of one turn number 14 wound around a 47 ohm, 2 watt resistor. RFC3 is the original choke with 1/4" removed from each end.

the final showed signs of instability even after neutrilizing. This proved to be parasitic oscillations-parasitic chokes in the plate leads cured this problem. The driver was also unstable-the original 11 pF butterfly driver capacitor was used to reduce the cost of modification, but this capacitor produced too much feed back due to the configuration so a new double section capacitor had to be used. Since a small capacitor with low capacity was not available on the market, a small bracket was fabricated and two Johnson type 160-140 capacitors were ganged for this job. This arrangement provides good isolation, takes up a minimum of space and gives more than adequate tuning range.

New local oscillator circuit

A new local oscillator and buffer were installed using a 6EA8. The triode section oper-

ates as a standard crystal oscillator with low voltage applied to the plate and the pentode section provides a small amount of gain and acts as a buffer to prevent frequency shift. A crystal switch and five sockets were installed to give additional coverage in the band. The crystal switch also has additional contacts to resonate the buffer coil when the oscillator frequency is changed—this adjusts the buffer output to maintain a constant injection level.

The crystal switch mounts in the hole where the tune switch was originally mounted; this tune switch was completely removed and the wires disconnected. The 12AV6 that was used as an audio oscillator is converted to an AGC amplifier.

Other transmitter changes

The basic exciter was left as original

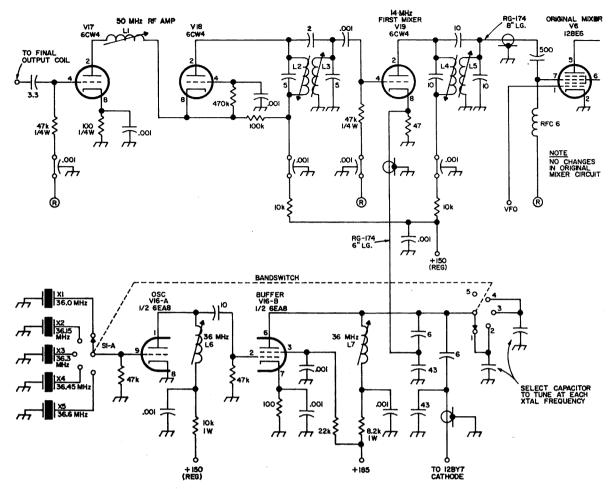

Fig. 2. Conversion of the SW 120 receiver to six meters. L1 consists of 10 turns number 26 closewound on a $\frac{1}{4}$ " slug-tuned form. L2 and L3 are both 12 turns number 26 closewound on a $\frac{1}{2}$ " form; L4 and L5 are 30 turns number 30 closewound on $\frac{1}{4}$ " form; L6 and L7 are 11 turns number 26 closewound on a $\frac{3}{8}$ " slugtuned form.

except for the minor changes shown in the carrier balance control and transmit-receive switch. Also, the VFO was adjusted to cover 14.0 to 14.150 MHz to the 12BY7 mixer. This was only done to use a crystal that was available. The original dial calibration was used with the 20 meter markings removed with a pencil eraser (don't use paint thinner). New markings were made to indicate 0-100 kHz and 150 kHz. When calibrated, the dial now can be read to 1 kHz and crystals can be selected to cover any 150 kHz range in the band.

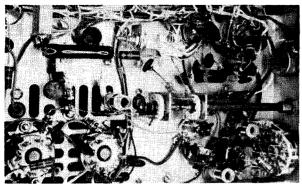

The original driver plate coil with associated capacitors is now installed under the chassis and connected to the grid of the 12BY7 mixer. A 10 pF capacitor is connected between the two coils—this forms a 14 MHz bandpass coupler for added rejection.

Transmitter modification

Before starting the conversion to six, a

preliminary check of the transceiver should be made to insure proper operation on the original band. Disassembly is accomplished by first removing all covers and the front panel. Mark any wires that may be disconnected. Follow these steps for removal of the unused parts:

- 1. Remove the final tube and all parts in the final compartment; leave only the plate and load capacitors and the two stand-off insulators.
- 2. Remove the 6DQ5 socket, disconnect wires and mark each with the pin number as it is removed. Pull the wires back through the chassis, but leave the meter wires in place.
- 3. Remove the driver plate coil and the associated wiring from pin #7 of V2 (12BY7) and driver tune (butterfly) capacitor.
- 4. Check to see that all parts from the driver plate and final grid are removed.

Closeup view of the new transmitter wiring.

The plate meter should also be removed before holes are drilled.

Mark the chassis for new holes by referring to the photos. Holes should be drilled with a small drill before enlarging for the chassis punch; use care when drilling so you don't damage parts left in the chassis. Holes for the crystal sockets require careful layout or much filing will be needed. New holes for the 6146 final tube sockets will have to be cut in the ventilation holes in the bottom of the final compartment. The tubes will now be mounted in the vertical position. Several stand off terminal strips must be installed for assembly of the new circuits; these holes should also be drilled before any parts are installed. When the holes have been deburred and all chips removed, the chassis is ready for installation of new parts.

Transmitter assembly and wiring

The new sockets can now be installed. If the 6146 sockets have no ground lugs, extra lugs will have to be installed. Install the mixer and driver coils as shown in photo-the new mixer coil is mounted under the chassis on an L-bracket. Position the terminals for direct connections. Wiring of the new mixer plate, driver, local oscillator and buffer should be done in sequence starting with the 12BY7 mixer plate. Be sure to leave room for the new driver capacitor and bracket. This capacitor should be installed last-refer to the photos and circuit diagrams for connections and layout. The new crystal switch mounts in place of the tune switch. Assembly of the final output circuit will require installation of a new coil with a better blocking capacitor. Start by installing the original neutralizing capacitor, modified plate choke and original dc bypass capacitor; position the parts as shown in the photo.

Modify the large loading capacitor by dis-

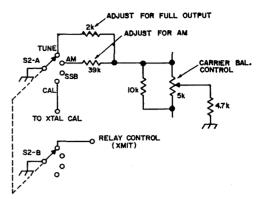

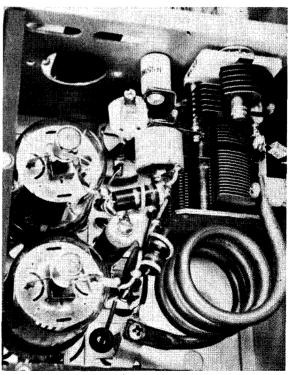

Fig. 3. Wiring the new function switch. S-2 is a double pole, four position rotary switch.

connecting the front half of the dual section. Use only the rear section. Remove two plates from the rotor and stator of the plate tuning capacitor and install the final tank coil. Use a brass strap from the stand-off to the plate tuning capacitor. Bend a "U" in the blocking capacitor bracket and install the new blocking capacitor. Also use a strap from the plate tuning capacitor as before.

Parasitic chokes must be used in the plate leads or the final will be unstable. Check back through all the wiring to insure that no wiring errors have been made. Be sure all bypass capacitor leads and socket pin grounds are very short. Use neat workman-

The new 50 MHz final amplifier showing placement of parts including the relocated rf choke. The small variable capacitor is connected in series with the original neutralizing capacitor.

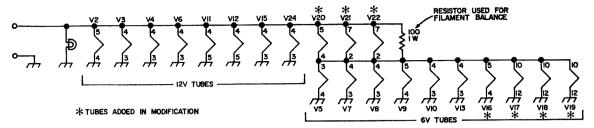

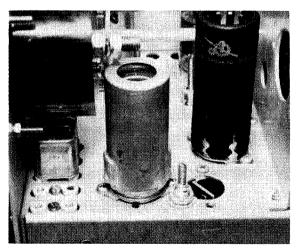

Fig. 4 New filament circuit for the modified SW—all others are original.

ship. Install the second mixer and driver plate tuning capacitor with a bracket, connect leads to the proper coils and install the front panel.

Receiver modifications

Since no room was available on the main chassis for the new rf and mixer stages, the 6 meter front-end and mixer were built on a small sub-chassis and attached to the VFO housing. This front-end consists of a 6CW4 cascode rf amplifier and a 6CW4 mixer. The local oscillator energy is injected into the 6CW4 cathode across a 47 ohm resistor. A double tuned output feeds the grid of the original 12BE6. The 6BA6 was originally used, but I found that the receiver had too much gain and excessive background noise. By eliminating the 6BA6 (V5) and feeding the first mixer directly to the 12BE6 mixer, the overall receiver gain is ideal. A very weak signal can be copied as well as on the more elaborate equipment I have available. The 14 MHz bandpass coupler must still be used between the two mixers for rejection of

The new local oscillator and driver tubes and crystal sockets are mounted below the meter. The extra hole in the foreground was evidently punched by a previous owner. Hole in the final compartment wall was for the original final socket.

120. The tubes indicated by an asterisk are added

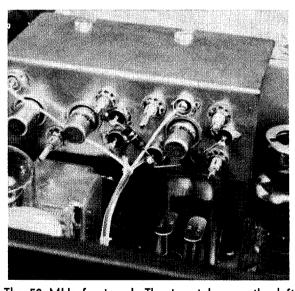

unwanted signals. A length of 50 ohm coax is used to couple the local oscillator injection and *if* output. The final output tank also serves as the receiver input. Coupling to the 6CW4 grid is provided by two 3 pF capacitors. On transmit the 6CW4 is cut off by switching bias to the grid as is done in the original circuit.

By referring to the chassis layout and circuit diagram, the new front-end can be built and checked out prior to installation. This completes the receiver changes except for the AGC and audio modifications.

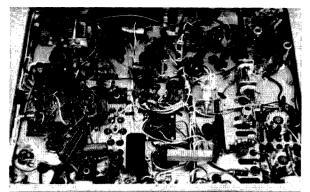

AGC and audio modification

As most persons know, the single band Swan has no AGC circuit or audio level control. With no control to hold the audio level at a pleasant volume, a loud signal blasts the operator out of his shoes before he can get the rf gain turned down. After using the transceiver a few days like this, I decided something had to be done.

In the original SW 120 the 12AV6 (V15)

The 50 MHz front end. The two tubes on the left are the cascode rf amplifier. A 3 pF capacitor connects from the feedthrough on the final compartment to the grid of the rf stage.

Under-chassis view of the modified transceiver. The local oscillator is in the upper right-hand corner, final sockets bottom right and mixer plate and driver center right. The new driver socket is partially hidden by the double tuning capacitor. The AGC circuit is next to the VFO dial plate. The new volume control and power switch are in the upper left-hand corner.

is a tune-up oscillator which generates a lot of excessive noise when tuning. This stage was converted to an AGC amplifier. Some early transceivers didn't have this oscillator.

The AGC system used is an audio derived method. The audio signal is sampled from the plate of the product detector and amplified. Finally, it is converted to a minus dc voltage which is proportional to the audio level. This voltage is than fed to the grids of the tubes to be controlled.

In this case the first rf and second if stages are controlled with the AGC loop. This allows the rf gain to be run full open. An audio volume control must now be used to adjust the audio level. The original rf gain control was moved to the hole which was occupied by the on and off switch. The new volume control with power supply

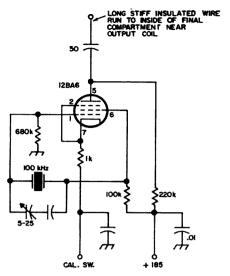

Fig. 5. Circuit of the 100 kHz crystal calibrator for the six meter Swan 120.

switch is now in the space left by the rf gain control. Two signals with extreme variations in strength now sound the same level in the speaker and very little popping or distortion is noticed even on loud signals.

The 50k pot marked AGC threshold should be adjusted with the antenna connectedadjust the control to give a residual voltage of -0.3 volts and a little kick on background noise from autos or static.

This AGC circuit works much better than any other version that I tried. I find it hard to give signal reports because most signals now sound the same strength. As stated previously, the quality of the stations received are still very good regardless of the signal level and I wouldn't be without AGC control. This circuit can be adapted to all the single band Swan transceivers whether modified to 6 meters or not.

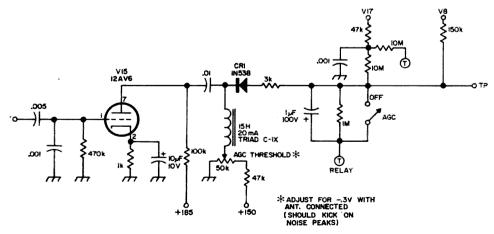

Fig. 6. Audio derived AGC system for the SW 120. This circuit is equally applicable to other single-band Swans.

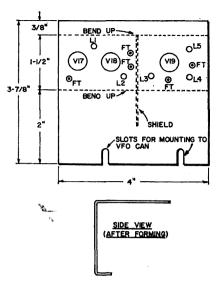

Fig. 7. Chassis for the 6-meter cascode rf amplifier and mixer circuitry.

Miscellaneous changes

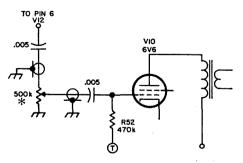

A new function switch is shown in the circuit diagram. This will allow the operator to insert carrier for different modes by simply turning the switch. Fixed resistors are selected for AM and tuneup modes.

A calibrator was installed for checking calibration. This switch is mounted in place of the old transmit-receive switch.

Adjustment and operation

Transmitter section

Preset all coils with a grid dip meter, disconnect the final screen and plate voltages, and check to be sure there are no short circuits and wiring is complete. Apply power and with the grid dip meter in the diode position, tune the local oscillator and buffer for maximum output indication. Turn on the transmitter, insert carrier and adjust the mixer and driver plate coils for maximum output at 6 meters. Set the VFO dial to the center of the range and peak up the 14

*MOVE RF GAIN TO OFF-ON POSITION MOUNT CONTROL IN HOLE MARKED VOLUME

Fig. 8. New audio volume control circuitry.

MHz bandpass coupler for highest level at 6 meters. Connect a voltmeter across the 10k bias resistor feeding the grids of the final tubes and again adjust all coils for maximum voltage on the meter.

Check to be sure the output is on 6 meters. The driver tuning capacitor should be set at near maximum capacitance for the low end of the band—this will allow coverage of 2 MHz or greater range. All coils should be peaked several times to make sure maximum output is obtained.

Neutralization

Connect a detector probe and VTVM to the final output jack. With the screen and plate voltages disconnected apply drive to the final and adjust the final plate and output capacitors for maximum reading. Next adjust the neutralizing capacitor for minimain output. Check to make sure the capacitor is not completely open or closed—it should be in the center range and the output reading low in relation to the original level. Now the screen and plate voltages can be applied and carrier inserted. Peak the driver tuning, connect the output into a good load, and tune up the final to about 230 mA with full drive.

Receiver

The new front-end should be adjusted for maximum gain before mounting to the VFO housing. Only slight peaking is needed for final adjustments.

The crystal calibrator is wired with a lead run into the final compartment and positioned about one-half inch from the final tank coil.

Final comments

This transceiver has proved to be a very worthwhile investment; the reports are excellent and it does a fine job. The final runs the same power as most other transceivers on 6 meters and will drive a 2 kW linear with power to spare. It makes a very handy rig for portable, mobile or just general use, and the Swan power supplies can still be used for fixed or mobile operation. With 6 meters looking up for the next few years, the VHF operator can get ready for lots of enjoyment from this conversion. Get your tools out and get to work.

Military Quartz Crystals for the Radio Amateur

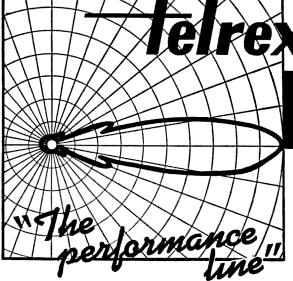

How to find crystal bargains

Surplus military quartz crystals are available at just about any frequency throughout the low and high frequency portion of the radio spectrum. These crystals can be very useful to hams and are available at modest prices from many electronic surplus houses or through some crystal manufacturers and dealers. Surplus crystals can be put to many good uses including transmitter and/or receiver frequency control, band pass filters, frequency standards and many others.

The writer has gathered together a lot of useful data on military quartz crystals and has presented it in tablular form (Tables 1 and 2). The information contained in the tables was derived from the "D" revision of the Military Specification MIL-C-3098, General Specification for Quartz Crystal Units. The table does not reference all of the 69, yes I said 69, types of quartz crystals used by the military. Rather, only the more common types frequently found in the surplus markets are discussed.

Holder Type	Pin Dia.	Pin Spacing	Holder Height	Holder Thickness	Holder Width
HC-5/U	0.156	0.812	2.205	1.817	1.594
HC-6/U	0.050	0.486	0.775	0.317	0.725
HC-10/U	0.062	N-A	1.055	0.560	N-A
HC-13/U	0.050	0,486	0.775	0.317	0.725
HC-18/U	0.017	0.192	0.530	0.150	0.402

Table 2. Operating characteristics of popular military quartz crystals.

The next time you visit your local surplus store on a crystal buying spree, bring along the tables. You will find that they will be very useful as you rummage through the bins.

Table 1 can be used when selecting the crystal type to match a particular socket

and vice versa. Table 2 provides much needed information for designing the oscillator circuit of a receiver or transmitter or when trying to select an appropriate crystal oven.

. . . WØHYB

Converting the BC-728

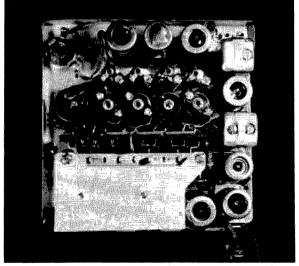

A low frequency superhet receiver for 160, 80 and 40 with a very attractive price.

One of the items you can sometimes find on the surplus market is the BC-728 receiver, a six tube superheterodyne battery operated unit for shoulder carrying. This unit is advertised by several dealers for the amazing price of \$7.95!

It is possible, for a bit extra, to buy the units complete with antenna, wet battery and charging cable. This antenna is a good deal if you are going to use the unit for portable use, the most logical application. This plugs into the antenna jack on one side, has a heavy cable with shoulder strap on it and the antenna fastens to the other side of the case. Thus the antenna feedline is used for the shoulder carrying harness. The antenna is telescoping for easy portability.

The case is rugged and most units are waterproof. If you have a selection you might pick out one with a sliding cover over the loudspeaker which would be very handy should you leave it out in the rain on Field Day.

The receiver has four pushbuttons inside to select the received channel. Channel one tunes from 2.0 to 2.6 MHz, channel two from 2.6 to 3.5 MHz, channel three from 3.5 to 4.5

Inside the BC-728. Note the large amount of elbow room. No crowding like most surplus gear!

MHz, and channel four from 4.5 to 6 MHz. While this was designed as a fixed channel receiver, you will find that there are tuning knobs right below each push button for tuning the channel. Thus, if you want to use the receiver for amateur use you can tune channel one, with a little padding, to the 160 meter band. Once you have peaked up the antenna and rf knobs you only have to tune the oscillator knob to cover the band.

Applications

For amateur band reception it is simple to slightly retune channel one for 160 meters. Channel three covers 75 meters as it stands, and channel four can be retuned to cover 40 meters quite easily.

Boating enthusiasts (or friends of boating enthusiasts) will find channel one worth more than the price of the whole unit for it covers the ship-to-shore bands and really brings them in with a wallop.

People having an interest in time and frequency standard signals (astronomy, piano tuning, watch adjustment, event timing, etc.) will find the receiver ideal. Channel one brings in WWV on 2.5 MHz, channel two tunes CHU on 3335 kHz, channel four tunes WWV on 5 MHz, and channel three can be retuned to bring in CHU on 7335 kHz. At least one of these should be available at all times of the day or night.

Conversion

Unless you are interested in wet nursing a wet battery it is a good plan to forget the beautiful vibrator power supply built into the case. This is designed to work with a 2 volt midget wet battery ("Keep upright when charging"). There is also a charging circuit with an external plug to go to a six or twelve volt battery. If you get the charging cable it should come with the battery clips.

Should you agree that dry batteries are

far better than wet (when one is inclined to forget about charging) then you can follow the next instructions. If you are planning to use the receiver for long periods then the wet battery would be a better deal, but for short periods of use dry batteries are ideal.

Step one: remove the power unit. Unscrew all of the bolts you can see coming through the outside case, bottom, top, back, and sides. Open the case and unscrew the knurled screw holding the antenna plug. This plate is also held by two small knurled knuts which will probably take a pliers to loosen. Lift the plate out and let it dangle. Unplug the power plug and gently lift the whole power supply, easing it out of the compartment. There is a little finger that extends into the power supply from the back of the case which will keep the unit from slipping out easily. You will have to work it out. Par for getting the unit out, counting all the screws and antenna plate, is six minutes.

The power unit can be relegated to the "junk box" for possible ravagement on future construction sprees. There are a lot of real nice goodies in it so don't give it the heave-ho.

Power cable

Your choice: remove the power connector socket from the power unit and connect the batteries to this or else remove the plug from the wires and connect them directly. If you decide to deplug the power line then keep track of the wires and connect them the same as you would with the plug.

Batteries

A number 6 dry cell is best for the filaments. They draw 300 mA at 1.5 volts, which will run down a flashlight cell pretty fast. And besides, there is plenty of room for the larger cell. A small 67½ volt portable radio battery will give more power than you need for the B plus and the drain is only 7 mA, so even the small #VS-016 batteries will give good life. You will also need a bias supply. Since there is no current involved here you can use small transistor radio or photoflash batteries. You will need about 7 volts, so a 7½ or 9 volt battery will do fine. Penlight cells, soldered in series are excellent and inexpensive.

Retuning the channels

Once you have gotten the receiver working and have checked out all the channels you are ready to retune. Let us take one specific channel and go through the process. For instance, if we want to move channel three so it will cover the 40 meter band, here is what we will have to do.

Since you will be about doubling the frequency of the channel you will have to remove about half of the windings from the three coils in that channel. Remove the shield can over the antenna coils and cut the connections to coil 3. The four small tongues can be bent back from the bottom of the coil form to release the coil. It is easier to remove turns when you have the coil right out there in your hand. Unwind half of the turns from the terminal end of the coil. Don't be afraid, make it a good generous half or you may have to pull it back out and pull off some more. Resolder the wire end of the coil to the terminal and put the form back into the set. Once the coil is soldered back in the circuit you can make sure you hit the right spot by checking it with a grid-dip meter and tuning the slug to both extremes to find out the new range of the antenna circuit.

Be very careful of the bottom end of the coil for if you should break the wire going from the terminal to the bottom of the coil you will have problems. The coil is wound with every other turn overlapped so that it is extremely difficult to unwind a turn or two from the bottom of the coil in order to give you enough wire to reach back up to the terminal. Better careful than sorry, to coin a phrase.

Step two is the rf stage. This is just as easy as the antenna coil. Do it the same way. There are not as many turns on this coil so you will only have to pull off about 30 turns instead of 40; run it down half way. Dip this one too if you have the instrument. Order a dipper if you don't have one so you'll be in better shape for the next conversion you try. Every ham shack should have a dip meter.

Now comes the p-d-r (piece de resistance), the oscillator. This coil is well shielded and, short of major surgery, you haven't a prayer of getting the coil out to work on. So? So work on it in the set. Warning: be careful. But don't worry, even if you louse everything up you can get back out of the predicament in a few minutes. Clip the wires going to the coil terminals from the set. Then clip the terminal board so that the two terminals are free. Next pry out the circular piece

that keeps you from seeing down into the coil. Watch yourself on this move for you can break off one of the wires of the coil which come through the two holes in the circular piece. The upper terminal (on the rf coil side) is the bottom end of the winding. Lay that over the coil shield out of the way. Now reach down with a midget screwdriver and pull off the tape from the top of the coil. With that off you can unwind the coil turns freely. Pull off 35 turns. If you lose count don't worry about it. You can stop at any time and resolder the wires into the circuit and see where the oscillator is perking by turning on the set. A dipper won't give you much indication due to the coil shield.

When checking for oscillator range it is handy to have a signal generator on hand. This is another pretty basic piece of test equipment for the well run ham shack. Lacking this basic unit you can always tune in a distinctive signal and hunt for it on your regular all-wave receiver. Good heavens, don't you even have that?

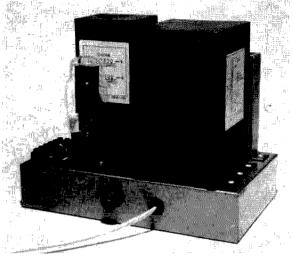

When you are all through pruning the coils it wouldn't hurt any to paint on a bit of coil dope to hold them together.

What's that Elmer? You say you broke the wire on the oscillator coil and don't know what to do. Well, in that case you can pull off all the wire from this coil and scrape the form as clean as you can. Then you wind up a new coil for yourself out of #31 enamel covered wire (or #29, 30, 32 etc.) and slip it over the form, holding it in place with the aforementioned coil dope. About 35 turns should do.

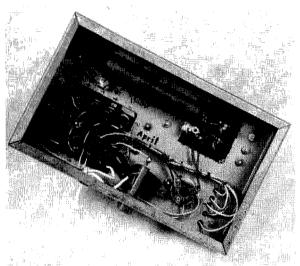

Antenna

The AN-75-C antenna, which was designed for the BC-728, is the best deal, but you may have some trouble locating it. For some obscure reason the antennas seem to have gone one way and the receivers another, though both are available in quantity. Should you decide for one reason or another to do without the AN-75-C you can get fine results by connecting a short length of wire to a Motorola type plug. Fifteen feet works well. You can coil this up and carry it inside the set when not in use and then fling it up into a nearby tree or house for operation. Or you can put a clip on the end of the wire and connect onto more ambitious wires. When changing antennas remember to open up the set and retune the antenna circuit for maximum volume.

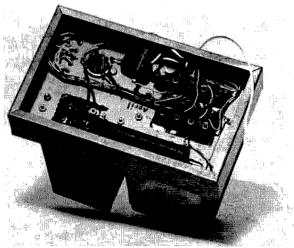

W. R. McCullagh VE3DAN McCullagh Studio 73 Simcoe Street Toronto, Ontario, Canada

Power supply. The picture was taken with Ilford Pan F film in the 4×5 inch camera. There was one spotlight overhead.

Bottom view of power supply. The camera used was a Cannon FX with a 50 mm lens. Photofloods in reflectors, no diffusion. Tri X film.

Underneath the power supply. The 4 x 5 inch camera was used, with diffused lighting.

Photographing your Electronic Gadgets

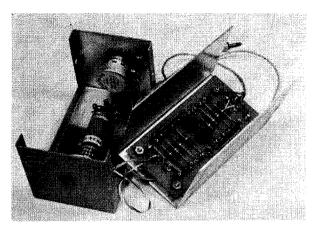

Practically every article in radio publications uses at least one photograph. Some of these are good, some are excellent—but a lot of them are poor. Yet I have never seen an article on how to photograph equipment properly, so here goes.

The amateur writing about his electronic gadgets is naturally going to use whatever camera equipment he has. If he did have a choice of equipment what would be best? A large view camera with tilting front and back, even if it is an old one, is tops; with this he is able to correct converging verticals.

The professional photographer uses a 4 x 5 or 8 x 10 inch camera, but it is possible to take good photographs with a box camera. A tripod or camera stand is a must, the heavier and sturdier the better.

Almost any lens will take a good photograph when closed down, as it should be to get everything in focus. For the small camera a long focus lens is best, except for detailed close-ups.

Lights don't need to be elaborate; photofloods in reflectors, reflector floods and even an ordinary lamp hand held is quite usable, as is the ordinary room lighting. Flash lamps

Balanced transistor amplifier for photovoltaic cell light meter. This shot was taken with a 4 x 5 inch camera.

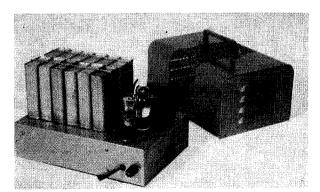

aren't very good and electronic flash isn't much better unless you really know what you are doing.

As the camera should be on a stand or clamped to something solid, fast film isn't necessary. For a small camera slow, fine grain film usually makes a better enlargement, although some of the newer fast films, such as Kodak Tri X, are excellent. Don't forget the exposure meter; most camera users have one and should know how to use it.

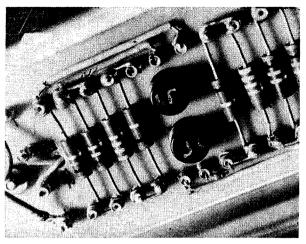

If you are using a view camera, don't forget that a close-up photo requires more exposure. See your camera manual regarding this. This is needed because of the additional bellows extension.

For a background, use a white card or unwrinkled white paper available from art supply houses.

Most editors like a large print, preferably 8 x 10 inches, so an enlarger is needed unless a friend or drug store is making the prints.

High voltage flash unit, with protective cover. A 4 x 5 inch camera with two diffused lights was used.

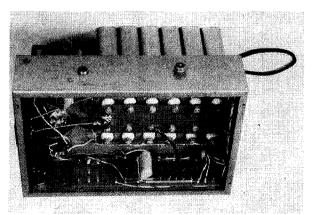

Closeup of a balanced transistor amplifier. The camera—Edixa reflex, with a Novoflex 35 mm lens. Tri X film.

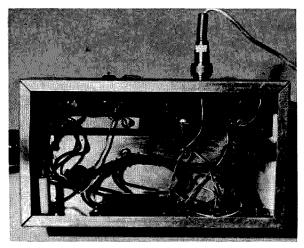

Reflectors to lighten up shadow areas may be white cards or even a newspaper and some diffusing material such as tracing paper or cloth, although glass cloth is the preferred material.

Looking over a number of radio magazines the most common faults in the photographs seem to be blurring, probably due to improper focusing or movement of the camera; and brunt out faces, due to having a flash on the camera too close to the subject. We musn't rule out poor engraving and printing, over which the photographer has no control. However, if the prints submitted aren't overly contrasty or soft and mushy, but are sharp and have a full range of tones from lights to darks, the chance of good reproduction is good.

Which brings up to the subject of process-

Inside view of the high voltage flash unit. The large connector is used because of extremely high currents which may peak at 800 amperes at 2500 volts. Definitely not for the beginner.
